BEADLE, or BEDEL, beed-del (Sax bydell, a messenger; Fr. bedeau; Span. bedel; Du. bedelle).—Junius derives it from bidd, beadan, to hid, to tell, to order; because he proclaims and exercises the will of his superiors. In this sense, bishops, in some ancient superiors. In this sense, bishops, in some ancient MSS, in the Saxon tongue, are called bedels of Gra MSS. in the Saxon tongue, are called bedets of Good (Obei bedelli). The term beadle, as now commonly accepted, is an officer chosen by the vestry of a parish, and whose business it is to attend the vestry, to give notice of its meetings to the parishioners, and execute its orders. The church beadle was formerly a kind of verger, whose station, in the 13th century, was at the door of the church, his dress being, as now, a blue gown. The name has since been changed, and he is now called a summoner or apparitor. universities, the bedel is an officer who walks before the masters at all public processions, &c., with a mace.

the masters at all public processions, &c., who a nance. Brans, backs (Ang.-Sar.bcde, prayer), among Roman Catholics, are small balls of glass, ivory, or other substance, strung upon a thread, and used to count the number of prayers repeated. The beads are distinguished by their size and shape; the larger ones being for Paternosters, the smaller for Ave-Marias. (See BOSARY. A beadenan is a prayer-man, one who prays for smother; and a bidding of the beads is a charge given by a priest to his parishioners, at certain times, to say so many Paternosters upon their beads for a soul departed:—

\* Tell your beads, says the priest, and be fairly trussed up

For you surely to-night shall in paradise sup."

pan heated to dull redness, and stirred about till they assume, a rounded form, from their edges becoming partially melted. When cool, the sand and charcoal, which have prevented them from collapsing, is descred out. Bugle-beads are simply cylinders of glass four or first times their diameter in length, which are out from a long tube, and used without any further preparation. Beads are also made of various hard seeds by drilling a hole through their centre. They are also turned from coral, ivory, bone, amber, and hard woods. Beads of all kinds are much used as articles of commerce in trading with savage nations, by whom they merce in trading with savage nations, by whom they are much sought after for purposes of ornament. Heads were anciently much used as ornaments, and are, at least, as old as the Egyptians.

BRADS, ST. CUTHDERT'S, a popular term for the detached head-like joints of the fossils called excinites (which see). They are found in great abundance on many parts of our coast. The legend associating St. Cuthbert with these fossils is thus alkaded

to by Sir Walter Scott :-

"On a rock by Lindisfarne, St. Cuthbert sits and toils to frame The sea-born beads that bear his name."

Bragle, bee'-gl, a small hound, more remarkable for perseverance than speed, employed in hare-hunting. The precise history of the beagle is involved in some obscurity. By Skinner the term is derived from the French bugler; and Menage is of opinion that as the hound was sent from Britain into Gaul, the name may be of British origin. Says Blaine, in the "Ency-clopedia of Rural Sports," "there are even now several varieties of lesgles, but formerly there appear to have been several more, from the deep-flewed diminutive type of the old southern bound, to the fleet and elegant foxhound beagle; to which may be added the pigmy breed called landog beagles. Beagles were formerly distinguished by the rough and the smooth. The rough wire-haired, or terrier besgle, is now seldom met with, though it was a hardy and altogether a vermin-loving breed, and very strongly formed. We were once traveiling on horseback along a turnpike-road, when our cars were struck with a screeching, and the unmusical

BEAGLE.

zaille of a pack of full-sized rough beagles, and we shall not easily forget how gallantly they rushed through both hedges, and how true to the line they carried the seent across the next field. We were told, on inquiry, that 300 guiness had been refused for this pack. North country beagle is a nimble and vigorous bound: the pursues the hare with impetuosity, giving her no time to double; and should the seem lie high, he will with ease run down two brace before dinner. Colonel Thornton, an eminent English sportsman, owned a Thornton, an eminent English sportsman, owned a valuable breed of minute lapdog beagles, and George IV., while prince of Wales, was in the habit of hunting with packs of well-selected dwarf beagles. Another well-known English sportsman, the late Colonel Hardy, once had a pack of beagles amounting to ten or twelve couples, and so diminutive in size that they were always carried to and from the sporting field in a large pair of panniers slung across a horse. This curious pack was not to the according weekles required to the couple of the second in which we have the second in the second Brads.—The manufacture of beads is carried on principally at Murano, near Venice, and at Birmingham. Glass tubes, of different colours, are first drawn out to various sizes; they are then chipped into small cylindrical pieces, which are put into a mixture of sand and charcoal, and stirred about until the boles in them are filled; they are then placed in a state of the panuiers stolen; and notwiththe boles in them are filled; they are then placed in a standing the most diligent search, no trace of either

would ever be discovered .- Ref. Blaine's Encyclopadia

of Rural Sports; Brown's Anecdotes of Dogs.
Braz, or Braz-Brad, beek, that external part of a ship before the forecastle which is fustened to the n ship before the forecastle which is fastened to the stem and supported by the main-knee. It was made of wood and brass, and nilited to the prow, for the purpose of damaging the vessels of the enemy. Since the invention of gunpowder, these strong projecting pointed beakers have fallen into entire disuse, and teak-head now signifies a small platform at the forepart of the upper deck, generally placed the same neight from the deck as the port-sills.

Branders, beel-kers (Ger. becher).—Glass vessels of a cylindrical shape, well annealed, and perfectly even in their substance, used by chemists for boiling or heating solutions. They should be very this, and without any purity-mark, or inequality at the bottom. Brand, been (Sax. beam, a tree).—The beams of a ship are strong thick pieces of timber, stretching across the ship from side to side to support the decks and

the ship from side to side to support the decks and retain the sides together. The main-beam is next the mainmast. The greatest beam of all is culled the midthin beam. When a ship inclines so much to one side that her beams approach to a vertical position, she is said to be on her beam-ends. In the measurement of a ship, the term beam is used to signify oreadth at the a sup, the term beam is used to signify breadth at the wales. (See Tonnage.) In mayal affairs, "on the starboard beam" signifies any point out at sea which, viewed from the stern, is at a right angle with the keel, and upon the starboard or right side of the ship. In like manner, "on the larboard-beam" signifies on the larboard or left side; "on the weather-beam" signifies that side of the weather-beam." signifies that side of the vessel which is towards the

BEAM, in Arch., may be either a large piece of timber or metal used for sustaining a weight, or to counteract two equal and opposite forces. Generally, it is the largest and principal piece in a building; and one of its most common uses is to support the main rafters.

BEAM-COMPASS. (See COMPASS.)

Bram-Engine.—A steam-engine which communi-cates motion by the top of the piston-rod, being con-nected with a beam or lever moving on a central pivot, the other end of the beam being in similar connection with the crank of the driving-wheel. In the directaction engine no beam is used, the piston working the crank.

BEAM-TREE. (See PYBUS.)

HEAN, been (Sax.), the common name for several le-guminous plants yielding pulse. These will be described under the names of the genera to which they belong; under the names of the genera to much they belong; thus, for bread-bean, see Faba; kidney-bean, scarlet-runner, and haricot (Phaseolus); ordeal-bean (Doli-Chas); Tonquin-bean (Different).

Bran-Caper. (See Zugorbullum)

Bran-Kang, in the early customs of this country,

was the title of the person who was chosen as king of the social festivals on the evening of the Twelfth-day. The mode of election is thus described :- A cake baked with a bean and a pea concealed in it, and is divided among the company present, when he that receives the bean is king of the cerumones, and she that has the pea is queen. (See Twelfelder.)

" Now, now the mirth comes, With the cake full of plums, Where bean 's the king of the sport here; Besides, we must know The pea also Must revell as queen of the court here." Herrick's Hesperides.

A like custom prevails in other countries. In France the twelfth-cake is plain, with only a bean, the drawer of the bean being king or queen of the feast. In Germany, the feast of the Three Kings (in allusion to the wise men of the East), on Twelith-night, is of a similar kind, and attended with similar ceremonies.

BEAR, buir (Ursus).—Bears are generally inhabitants of the wooded districts of mountainous countries. and occur in all parts of both hemispheres, with the exception of Australia. Of all the carnivora, they are the most omnivorous in their diet, some of them living

bear; but, more than all, he delights in honey, to rebear; but, more unb an, ne uniques in many as a stable he strongholds of wid bees, though not uncommonly compelled to beat a retreat before the tiny sting-bearers. Generally, the bears are large heavy animals, with an awkward and shuffling gait. Their auterior limbs, however, are also and admits their descriptions. and shuffling gait. Their anterior limbs, however, are possessed of considerable mobility, and, despite their bulk and great weight, they exhibit great dextorfly is climbing. The bear was not so meanly treated by our climbing. The bear was not so meanly treated by our sancestors as by us; by them, his strength and fiercesess were acknowledged, and a stone castle was built for his lodging. To bait him with savage mastiffs was thought Ilt game to set before the king; and, to this end, th were founded, at Southwark, in Paris Gardens, as it is still called, two circular buildings, somewhat after the style of the ancient Roman amphitheatre. The buildings were unroofed, and contained tiers of seats buildings were unrosted, and contained tiers of seats for the company, with a pit in the centre. The admission to the ordinary part of the bear-garden was one halfpenny. In the reign of James I. it was under the protection of royal patent, granted to the holders "for the sole practising and profit of the fighting and combating of wild and domestic heasts in England, for the term of fourteen years." Edward Alleyn, the celebrated actor and founder of Dulwich College, enjoyed this patent for several years. The practice of granting a bear-fighting license was abolished in 1642, and the hear-master for the time being committed to Newgate for the crime of threatening to cet the tbroat of any man who voted his bear-garde at the strong "Wild" man who voted his bear-garden a nuisance."-Wild Sports of the World. The feet of the bear are armed sports of the World. The text of the bear are arrand with formidable curred claws, equally available for tearing a carcass or digging up a root. In the grisly bear (Ursus ferox) these claws possess the singular property of independent action, each separate claw being as capable of distinct movement as the fingers of the human hand. The strength of this lastmentioned animal is so prodigious, that it can bear off a cover him or the strength of the start. an ox or bison weighing a thousand pounds. Should it find a carcass, and, being already full, have no immediate appetite for it, the grish bear will dig a pit and bury it. This propensity to bury is very peculiar. and bury it. This propensity to bury is very peculiar. Bear-hunters suddenly overtaken by the animal have stretched themselves along the earth and feigued death; whereon the shaggy sexton has immediately set about excavating a pit, into which the hunter was rolled and covered with earth. It is said that wolves, however famished, will not touch a body buried by a grisly bear, though they will devour any and the vilest offal chance may throw in their way. Another peculiarity of the animal in question is, that he does not hug his prey. His claws are broad, of great length, and edged like a chisel. Eyeing the object of attack intently for a moment, he rushes at it, rears, and strikes with his tremendous fore-paws. Sir John Richardson mentions the case of a hunter who was completely scalped, the skull being laid bare, and the hair turned right over the face, by a blow of the grisly bear's paw. The polar bear equals in size and strength the grisly bear; indeed, Lanont, the most recent of Arctic explorers, was assured by the Spitzbergers that a full-grown polar bear would attack and kill a bull walrus three times its own size; stacts and kill a bull walrus three times its own size; the bear's hunting tactics being to conceal itself belind anics-hillock, and watching till the walrus came floating past, spring on its back, and helding on by its teeth to the creature's neck, batter in the skull with repeated blows of its tremendous fore-paws. The polar hear, whose whole life, almost, is passed on the slippery ice, has the soies, as well as the rest of its feet, covered with hair. The respect with which, in some countries, the bear is treated is very curious. When the Lap starts on a bear-hunt, he doe's so with When the Lap starts on a bear-hunt, he does so with as great a show of solemnity as if he were going to the funeral of a dearrelative. When the bearis discovered, and the attacking party are driving at it with their spears, they, the while, chant a supplication that the spears, any, the wine, count a supplication that the bear will not take it amiss, and imploying him not to hurt them. There is no such thing as rejoicing over the death of their cuemy. They are airsid even to mention him by name, and allude to him, when obliged, as the old man in the fur cloak." Sir John Richardson relates a story of an old Indian and his wife, who, while sitting on the bank of a narrow stream, looked up to a mon-strous bear facing them on the other cide. Having no almost entirely on animal food. Roots, berries, worms, strous bear facing them on the other ride. Having no thesects (especially ants), are equally relished by the weapon wherewith to attack the animal, the Indian

made an appeal to its better nature. "Oh, bear made an appeal to its better nature. "Oh, bear," said he, "I uever did you any harm; I always had the highest respect for you and all your relations. Pray go away and do not molest us." And the bear went away, moved, as the Indian firmly believed, by his eloquence. Captain Lyon has furnished the tollowing account of the hybernation of this species of bear, derived from an Esquimaux. At the commencement of winter the pregnant she-bears are very fat, and siways solitary. When a heavy fall of snow sets in, niways solitary. When a heavy fall of snow sets in, the animal seeks some hollow place in which she can lie down, and then remains quiet while the snow covers lie down, and then remains quiet while the snow covers her. Sometimes she will wait until a quantity of snow has fallen, and then dig herself a care: at all events, it seems necessary that she should be covered by, and lie amongst, snow. She now goes to sleep, and does not wake until the spring sun is pretty high, when she brings forth her two cubs. The cave by this time hus become much larger, by the effect of the animal's warmth and breath, so that the cubs have room enough to move, and they acquire considerable strength by continually sucking. The dam at length becomes so thin and weak, that it is with great difficulty she extricates herself, when the sun is powerful enough to extricates herself, when the sun is powerful enough to throw a strong glare through the snow which roofs the den. The Esquimaux aftirm that during this long confinement the hear has no evacuations, and is herself the means of preventing them, by stopping all the natural passages with moss, grass, or earth. The natives find and ki'l the bears during their confinement by means of dogs, which scent them through the snow, and begin scratching and howling very eagerly. As it would be unsafe to make a large opening, a long trench is cut, of sufficient width to enable a man to look down and see where the hear's head lies, and he then selects a mortal part into which he thrusts his spear. The old one being killed, the hole is broken open, and the young cubs may be taken out by hand, as, having tasted no blood, they are then very harmless and quiet. Sir Emerson Tenneut relates, that among the Cingalese there exists a belief that certain charms are efficacious in protecting them from the violence of bears; and that those accustomed to expose themselves to encounters carry a talisman, either attached to their necks or enveloped in the folds of their bair. (Ceylon, vol. i.) The black bear of America (Ursus americanus) is smaller than most of the family. Its head is narrower than that of the common brown bear, its ears wider apart, its muzzle more prominent, and it lacks the depression over the eves. The fur is comit lacks the depression over the eyes. The fur is composed of short smooth hairs, which are of a glossy black for the greater part of their length, instead of comparatively grizzled fur of the brown bear.— a value vame arranged to the sain of the black bear, -a vame that has very much decreased, for the skin that once totohed from twenty to forty guineas is now worth scarcely as many shiftings, -and the high esteem in which the Indians held their flesh, caused great havor amongst them. The importation into England in 1783 was 10,500 skins, and ascended gradually to 25,000 in 1808, since which time there appears to have been a considerable decline; as, in a table of exports and imports of skins into Great Britain, published in the catalogue of the first Great Exhibition, the number of bear-skins is 9,500. Of these, 8,000 are again exported; so that the annual consumption in Great Britain is 1,500 only. It is chiefly used in this country for military purposes; as for caps, pistol-holsters, &c. For this reason the animal is frequently called the "army" bear. Inhabiting the Cordileras of the Audes, in Chili, there is a bear called the Byectaded bear (Urans ornatus), on account of two semicircular marks round the eyes, reminding the beholder of spectacles. This naimal is entirely black, with the spectacles. This animal is entirely black, win the exception that its muzzle is tawny yellow, and the upper part of the breast inclined to grey. The Syrian bear (Urune syriacus) is probably the oldest on record. This hear it was that averaged the scoffing of the children at the prophet Elishs. The colour of the Syrian bear is stated by some to be brown, and by others to be white, spotted with fulvous white. These children's however, are supposed to have been occa-Dear (Draws syrtaces) is processly the collect on the present. This hear it was that averaged the scoffing of day to let the entire beard grow, when mearning, for the children at the prophet Elishs. The colour of the Syrian bear is stated by some to be brown, and by estimation among the Jews, as is is until the present to be white, spotted with fulvous white. These charges, however, are supposed to have been occasioned by the abrasion of the long hair, whereby the most solemn out of a Jew or a Mahomedan. Nearly would for beneath becomes exposed. It is a ravenous all the Eastern peoples prided themselves upon the

beast, and will without accuple attack and destroy the smaller mammalia. The sloth bear is one of the most singular of the family. When first introduced to this country, about sixty years ago, it was supposed to be a sloth, and was so named. Bewick, in his "Quadrucountry, about sixty years ago, it was supposed to no a sloth, and was so named. Bewick, in his "Quadrupede," gives a portrait of the sloth bear as an animal that had hitherto escaped the observation of naturalists. It is about the bulk of the brown hear; but its ragged-looking hide gives it the appearance of heing larger. The fur of the sloth hear is black, with here and there some brown spots, and two white streaks under the side of the sould under the side of the neck, bearing some resemblance under the side of the neck, bearing some resemblance to the letter V. The cartilage of its nose is capable of extension, and the lips of considerable protrusion. Its food consists of wild fruits, honey, and white ants; and it generally selects for its home some rocky and solitary cavern. The bear family constitutes a natural group of the Plantigrade mammalia. It is characterized by six incisor and two canine teeth in each jaw; twelve molars in the upper, and fourteen in the lower jaw; heavy body, covered with a thick woolly coat; a large head, terminating in a prolonged snout, with very extensible lips. The tongue is smooth, the ears of moderate size and rather pointed. The feet are all pentadactyle, or five-toed, armed with strong claws, well suited for burrowing. The tail is short. Despite their enormous physical power, the bears exhibit but a small carnivorous development.

BEAR, To.—To bear down upon the enemy, to have the advantage of the wind; or being to windward, to approach the enemy by sailing large, or from the wind. To bear in with the land, implies to stear a ship towards the land; to bear off from the land, signifies to steer a ship from the land, lest she should accident-ally run aground when under sail. To bear up, or bear away, is to change the course of a ship, in order to make her run before the wind after she had

sailed some time with a side wind. To bear a hand, implies to make haste, to use dispatch.

Bear, on the Stock Exchange, is a term applied to one who, having sold stock or shares which he does not possess, is anxious that such securities should de-cline in value, so that he may be embled to buy at a profit. The term is said to take its origin from the atory of the man who sold the bear-skin before he had killed the bear. The term bearish is also used to denote a man's opinion that prices will fall,

BEAR-BEATURG. (See BAITING.)
BEAR-BERRY. (See BAITING.)
BEAR-GARDEN was the name given to the place where, formerly, bears were kept and publicly baited; and in the present day it is sometimes applied to a well the place of the place where, for the place where, for the place where, for the place where the place where

rude, turbuleat assembly.

BRAE-LEADES .- Formerly at fairs and country festivities one of the great attractions was a dancing hear, which was muzzled and led about by a man who was called the bear-leader. The practice is now abolished on account of its dangers. The term of bear-leader, on account of its dangers. The term of bear-leader, however, is still applied in a facetious sense to a tutor or guardian who takes charge of a young man of

wealth or title in his travels.

weath or title in his craves.

Beard, beerd (Aug. Sax.), the hair growing upon the chin, and other adjoining parts of the face, in man; and sometimes, though very rarely, in women. It is thicker than the hair of the head, but longer, when suffered to grow, than the hair on the other parts of the body. It is usually of the same colour as the hair of th head, but always the same as that of the eyebrows. The beard is most abundant among those of the Cancasian race; and many persons, natives of Africa, America, and Australia, have little or no beard. The earliest notice on record regarding this manly ornament is in the Bible (Levit. xix. 27), where the lawgiver of the Jews warns them not to "mar the corners" of their beards, but to let them grow after the Egyptian fashion, leaving a little tuft of hair at the extremity of the chin. These Hebrews, who are as tenacious of ancient customs as the Chinese, continue to the present

fashion and form of their beards; and we have it expressly on record, that the Assyrians and Persians indulged in very long beards; and that often, and particularly their kings, they interwove the hair, the lower lip, and chin, with matted gold.—(See St. Chrysostom, Opera, xi. 378, ed. Monf.; Hill's Ottoman Empire, p. 48, 1709; and Layard's Ninevek and Persepolis. p. 45, 1709; and Layard's Niseveh and Percepolis.)
A good many of the ancient Egyptians, and particularly their kings, are often figured in the delineations of them which have come down to us, as entirely without beards. Beard-cases were often, as in the Memon's head in the British Museum, employed to conceal all the hair that was permitted to grow on the faces of this people. Among the Greeks, and especially among the Greek philosophera, this ornament was held in high estimation. Athenœus tells us that the Greeks were the beard until the time of Alexander the Greeks who ordered his Manedonian soldiery to sheep it. who ordered his Macedonian soldiery to shave it off, lest the growth of it might give a ready handle to their enemies in battle. Philosophers have nearly always affected the beard as a mark of gravity, and even venerableness; and Strabo tells us that the Gymnosophists of India wore it long. Socrates and Plato were honoured with the distinction of "bearded master" by their pupils; and the origin of the proverb, ek pogon of sophof (wise men, from their beards), arose from this class of wise men among the Greeks indulging always in this ornament. The Romans were the beard until the 5th century A.C.C., when Publius Ticinus Mens brought over a colony of barbers from Sicily to exercise their profession on the Roman chins. Augustus, and the Roman emperors till Hadrian, shaved their beards; and Plutaroh says that Hadrian allowed his to grow to hide the scars on his face. All the imperial personages after Hadrian grew their beards. It was customary, on the assumption of the toga virilis among the Roman youth, to consecrate the flust-fruits of their beards to some deity. Homer and Wirell Chambines and Blief the recovers Pletarch Virgil, Chrysippus and Piny the younger, Plutarch and Strabo, Diodorus and Juvenal, Perseus and Pru-dentius, all celebrate this ornament on the faces of persons distinguished for the length or whiteness of their beards. The most curious story of long beards their beards. The most curious story of long beards is that of a Middle-Age personage, John Mayo, the bearded by pre-eminence, who was an exceedingly tall man, and nevertheless, when he untied his beard, it flowed down upon the ground; and the emperor Charles V. is said to have been greatly amused by the wind making it fly in the faces of the lords of his court. The Lombards (or Longbeards), the early French, the ancient Britons, and the Anglo-Saxons after they con-quered Britain, all nourished the growth of their beards with peculiar care. The English clergy by and by (see Knight's History of England, vol. i. pp. 136 and 165), probably in imitation of those of Western Europe, began to shave the beard, and until the time of Wil-liam the Norman, the whole of whose army shaved the ham the Norman, the whole of whole army shaved the beard, there prevailed a bearded class and a shaven class, a laity, in short, and a clergy in England. When Duke William conquered England, he insisted rigor-ously upon carrying out the Norman custom of shaving; and he thus constrained many of the high-spirited Britons rather to abandon their country than their whiskers. But by-and-by they got the advantage of their ruthless conquerors; and the higher classes indulged in the moustache, or the entire beard, from the reign of Edward III, down to the time of Charles II. Beards of particular cut were often characteristic of a profession. Thus, there is the steeletto beard, and the profession. Thus, there is the secretar beard, and the spade beard, and the "beard of the general's cut," of Shakespeare. (See Henry V., iii. 6.) Taylor, the "water-poet," in his odd, humorous way, thus speaks of the beards of his time in his "Whip of Pride"—

Some like a spade, some like a fork, some square, Some round, some mowed like stubble, some stark bare,

Some sharp, stiletto-fashion, dagger-like, That may, with whispering, a man's eyes outpike."&c.

In the reign of Charles II. the entire face was often shaven; sometimes aslight moustache was tolerated, and sometimes the whiskers or hair on the cheeks was grown. In France it went out of fashion in the reign of Louis XIII., to be inaugurated again by Napoleon's soldiers. In Russis it was highly fashionable until Peter the 237

Great's time, who cleaned all the faces in his empire.
"But such a veneration," remarks Dr. Giles Bletcher,
"had this people for these ensigns of gravity, that many
of them exercially preserved their beards in their cabinets, to be buried with them, imagining, perhaps, that
they should make but an odd figure in their grave with
their naked chins." During the last fifty years growthe whole heard has become very company it most their naked chins." During the last fifty years growing the whole beard has become very common in most European nations. First the practice began in Bonaparte's army, then it extended to Italy, then to Germany, then to Spain and Russia, and lastly, to England, where it is now very greatly on the increase.—(See the Lexicons of Hoffman and Pitiscus, the English Cycle-

padia, the Encyclopadia Britannica, &c.)
BEARER, bair-er, in Arch., a post, or brick wall, between the ends of a piece of timber, to support it.

BEARING, bair'-ing, in Mar., an arch in the sky intercepted between the nearest meridian and any distant object, either discovered by the eye and re-ferred to a point on the compass, or resulting from sinical proportion. It is also used to mark the situation of any distant object in connection with a ship's position. Sailors often take the bearings of another ship, or some object on shore, to save themselves the trouble of referring to the compass.

BEARING, in Mach., that part of a shaft or spindle which is in contact with the supports. Upon the correct adaptation of the rubbing surfaces to each other depends the value of a machine. If, for example, there should be much friction between the axle of s railway-carriage and its bearings, there would be a large amount of power lost in overcoming that friction. The mechanical force-motion retarded-would, ac-cording to the received theories of the present day, somewhat too hastily adopted, be converted into heat.

It has therefore been the study of engineers to produce bearings which should offer great resistance to pres-

bearings which should ofter great resistance to pressure, and, from their smoothness, produce as little friction as possible.—Ref., Ure's Dictionary of Arts, Mannfantures, and Mines, edited by Hunt.

Brasing Notes.—In the tuning of keyed instruments, harps, &c., bearing notes signify those notes between which the most erroneous or highly-tempered between which the most erreneous or highly-tempered fifth is situate, on which, also, the wolf's said to be thrown. Many tuners begin at C and tune upwards, through the progression of fifths, C, G, D, A, R, B, Gb, Db, and Ab, and then stop, and again at C, the octave above the former note, and tune downwards through the fifths F, Bb; and Eb, and thus the resulting fifth AbEb produces bearing notes, owing to each fifth having been made more or less flat than the extens of twelve notes will have the Leaf term of twelve notes will have the Leaf term of system of twelve notes will bear, the least sum of all their errors or temperaments being the diaschisma. Some tuners are in the habit of throwing their wolf into the fifth Ab, Db, and others into that of Db, Gb.

BEARING THE BELL, an expression conveying the idea of excelling in any art or pursuit. He that takes the lead in anything, or gains the prize in any contest, is said to bear away the bell from the rest of the competitors. The phrase originated from a custom in vogue in the 17th century, of giving a little bell of gold or allver to the winner of a horse-race.

BEASTS OF PARK, or CHASE, are, properly, buck, doe, fox, marten, and roe; but in common and legal sense extend likewise to all the beasts of the forest, which, besides the others, are reckned to be hart, hind, hare, boar, and wolf, and, in a word, all beasts of venery or hunting.—Beasts of warren are hares, conies, and roes.

BEAT, or BATTEMENT, beet (Fr.), a transient grace or ornament in the performance of a note, denoting that a kind of shake is to be made, by beginning with the half-tone below the given note, and quickly repeating the given note and that: on the contrary, the shake maked the affected by beginning on the note. shake marked tr is effected by beginning on the note above the given one (whether a half or whole tone distant), and repeating the given note and it alternately.

BRATTEICATION, be-ut'-i-fi-kui'-shon (L. beatus, happy, and facio, I make), in the Roman Catholic church, is an act by which the pope declares a person beatified or blessed after death. It is the first step to canonization, and no person can be beatified till fifty years after his death. All certificates or attestations of virtues and miracles, the necessary qualifications for saintship, are

Besting

Beauty

examined by the Congregation of Rites; and this ex-amination often lasts for several years; after which the pope pronounces the bestification. The corpse and relics of the future saint are forthwith exposed to the veneration of the superstitious, his image is crowned with rays, and a particular office is set apart for him. Bestification differs from canonization, in that, in the former case, the pope only grants a privilege to certain persons to pay religious worship to the beatified, without determining judicially upon his state; in the latter case, the pope speaks as a judge, and determines ex cathedra upon the state of the person canonized.

BRATING, beet-ing, in Mar., the operation of making progress at see against the wind in a zigzag line, or traverse. It-is generally understood to be turning to

\*windward in a storm or fresh wind.

BEATING THE BOUNDS, -On Ascension Thursday it is an old custom throughout England for the clergyman of the parish, accompanied by the churchwardens, to survey the old landmarks which show the bounda-ries of the parish. In this perambulation they are ries of the parish. In this perambulation they are accompanied by the boys of the parish school and their master. The boys carry willow wands, with which they strike the various boundary-marks. From this practice arises the term "besting the bounds." It was the custom in earlier times to whip a boy or boys at stated places on the boundary-line, in order that the remembrance of the place might not pass away when

he grew up.
BEATING TIME, in Mus., that motion of the hand or foot used by performers themselves, or some person presiding over the concert, to specify, mark, and re-gulate, the measure of the movements. If the time be common or equal, the beating is also equal; as, down, left up right, or one down and one up; if the time be triple or unequal, the beating is also unequal; as,

down, left up, &c.

Bratings. — Those regular pulsative heavings or swellings of sound produced in an organ, by pipes of the same key, when they are not exactly in unison, i.e. when their vibrations are not perfectly equal in velocity, not simultaneous and coincident, which, as Mr. Emerson observes, occasions a repetation of noises like waw, aw, aw, aw, aw, or ya, ya, ya, ya. These are called beats by Dr. Robert Smith, Mr. Emerson, and we believe every other mathematical writer that notices the phenomena. Earl Stanhope, in a letter in the Philosophical Magazine, vol. xxviii. p. 150, has laboured to make a distinction between the meaning of beats and beatings, in order to identify the former with the pulses or vibrations of the sounds themselves, and to denominate the above phenomenou by the exclusive use of the term beatings.

BRATTUDE, be-åt'-i-tude (Lat. beatitude, blessedness), denotes the highest kind of felicity or happiness of which human nature is susceptible,—that state in which the soul attains the utmost excellence and dignity of which it is capable, -the fruition of God in a future

"Above him all the sanctities of heaven Stood thick as stars, and from his eight received Bestitude past utlerance.

The Beatitudes is a term applied to Christ's Sermon on the Mount, from the blessedness that he there prononness upon certain characters of persons.

BEAT OF DRUK, in Mil.—Many of the movements and maneuvres of soldiers are indicated by a particular method of drum beating. There is a great variety of beats, of which the principal are as follows:—the general, giving notice to troops that they are to march ; the assembly, ordering troops to a rendezvous, or to join their colours; the march is the command to move, siveness with the left foot first; the tattoo, or toptoo, is the order to retire to quarters. The réceille is always besten at dawn, and gives notice to the soldiers to rise, to the sentinels to desist from challenging, and that leave is given to come out of quarters. To arms beats when soldiers are dispersed, in order to bring them together; and the retreat is a signal to retire from before the enemy; the retreat is also heaten in camp and garrison a little before cunset, and orders the soldiers to retire to their quarters. The alarm gives notice of sudden danger; and the parley demands a conference with the enemy.

basts; such as the chamade, the long roll, the rogue's march, the pioneer's call, the call to church, &c.

Brays.—The audible phenomenon attending the sounding of two notes at the same time, which sp-proach within certain limits to the producing of a concord with each other, which the late Dr. Robert Smith, in his "Harmonics," has applied with the happiest effect to the practical tuning of instruments, according to any given pratern or arrangements of the seconding to any given system or arrangements of the intervals. The phenomenou of beats forms also the means by which practical tuners unacquainted with theory or the exact comparative magnitudes of intervals, adjust the notes of organs, pisnofortes, harps, &c., by the judgment of their ear, in the daily exercise of the tuning profession.

Bearsonia, beel-so'-ni-d, in Bot., a gen. of plants belonging to the nat. ord. Frankeniacaa. The leaves of one species are used at St. Helena as a substitute

for tea.

Brau, bo (Fr.), is applied to one who pays too much attention to his dress and personal appearance; satirically he has been described as being "a woman in everything but the sex,—a man in nothing except the sex.

BEAUTY, bu'-to (Fr. beauté) .- The Beautiful, the Sublime, and the Picturesque go to form a portion of every theory of taste. No exact definition of beauty has ever been given, and we may be satisfied with a sentence descriptive of it. Beauty, then, is that which gratifies the taste of all. It springs most subtilly from our capacity of enjoyment, or from our sense of the pleasurable; and hence the unparalleled diversity of opinion which has always existed regarding it. The riew which appears to us liable to fewest objections is that of the late Sir William Hamilton, which is as that of the follows. He holds, with Aristotle, that pleasure, from which the sense of beauty ultimately springs, is the invariable concomitant of the unimpeded energy of a power. The most general causes which contribute to raise or lower the intensity of our energies, and, of course, by doing so, to exalt or diminish our sense of the Beautiful, in particular, are, -1. Novelty; 2. Contrast; 3. Harmony and Discord; and 4. Association. Taking up the feelings of man, and viewing them entirely as results or as effects of this energy, there is a contemplative class of them which springs from the combined action of the imagination and of the understanding, which gives rise to the pleasurable emotion which men ordinarily denominate beauty. The feeling of beauty is, then, the result of the combined energy of these two powers, the Understanding and the Imagination. But how de those powers act? The imagination, for example, presents the various objects in various lights to the understanding, which it, according to natural and inalienable law, combines into a whole, or into a unity. In contemplating a building, for example, which is reared pretty high from the magination of the pavement on which we walk, the imagination at once singles out its pillars, and turrets, and pinnacles, which the understanding at once, by leading their various properties up to its natural unity, pronounces the one brautiful, perhaps, and the other, it may be, deformed; and this altogether apart from their subserving any useful function in the building. Let us now step to the other side of the street, and survey the building from this point of view. Here one's eye can take in the whole building; and the mind now, instead of merely dwelling on isolated pillars, &c., hastens to take up the whole in its natural way, and pronounces it a beautiful or ugly design. Now there are various kinds of heauty, both of detail and of com-plexity, observable in this building, which must be dwelt upon, Take a pillar, for example: any one seeing it for the first time would pronounce it absolutely beautiful, irrespective of its having been the workmanship of human hands, and of its being probably designed to adorn and support some portion of a stately edifice. This is the absolute beauty of the pillar. But when it is regarded in all those subordinate lights, or, it may be, only in one of them, this is relative or dependent heauty. It is the latter species of beauty which is variable, not the former. All men admire the arters. The alarm gives absolute heavity of a rose, without being told that it has a three are several other nourishment and propagation of the plant. No doubt, as

Beauty soon as the botanist informs us of these circumstances soon as the botanist informs us of these circumstances, we add this new form of enjoyment, which has accidentally arisen round the rose, to our previous pleasure at its contemplation, and enhance in this way our original perception of its heauty. But, on the former occasion, it was the absolute beauty of the rose which we admired; now, it is the dependent or relative beauty of it. Probably, indeed, the gratification which we feel in the contemplation of a beautiful, of a sublime, or of a nicturescene object, arises from a consideration of a picturesque object, arises from a consideration of the individual object before us. No dependent the mutual topes there are as not uperature feelings, such as those which we have specified, or those of the desire of its possession, or of satisfaction at being the owner of it, should be allowed to interfere, at least with the free analysis of taste. The greater the number of parts in an object which the Imagination to the Understanding and the number of parts in an object which the Imagination holds up to the Understanding, and the quicked the latter power can unify them, the greater will be the pleasure afforded in the exercise, and, costeris paribus, the more beautiful will be the object. Now, this principle not only affords the rationale of what beauty is, it likewise enables us to explain the differences of different individuals in the apprehension of this quality in objects. Thus, if an individual of a quick, vigorous, cultivated mind, be presented to a beautiful scene, there can be no doubt as to his judgment of it; while, if a person of slow, rude, uncultivated nowers, as a boor. person of slow, rude, uncultivated powers, as a boor, be presented to the same scene, he will likely take no interest in it, or, it may be, he may pronounce it posi-tively ngly. It is this principle, acting under the pecu-liar law of association, which explains all the diversities of tasta between a Chinese and an Englishman, for example. Peculiarities of climate or of historical association, &c., combine themselves with the native sense of taste of each nation; so that, what one would call beautiful, another would call deformed; and what one would designate peculiarly agreeable, another would say was particularly ugly. It is, besides, another law of taste, that it is quite a different thing to separate a of taste, that it is quite a different thing to separate a whole into its parts, and to separate a whole into its lesser wholes. Thus, nothing but disgust would be produced if we would think of anatomizing a beautiful face into its integuments, muscular fibres, and bloodvessels, &c.; while we can readily analyze the same face into its various features of brow, eyes, nose, cheeks, and mouth, and, it may be, put those different parts together again with more delight than we analyzed them. The feating of neasure in the Sublivia is lyzed them. The feeling of pleasure in the Sublime is essentially different from the feeling we experience of the Beautiful In the latter, one enjoys unmingled pleasure; in the former, this pleasure is mixed with pleasure; in the formula, and plant Magnitude is an essential condition of sublimity, whereas with beauty it is an impediment. The vast, the wild, the formless, are often sublime, while they are by no means beautiful. Sublimity is three-fold,—the sublime of Space, the sublime of Time, and the sublime of Power. The Picturesque again stands in somewhat of a similar relation to the Beautiful as the Sublime does. When the imagination and the the Sublime does. When the imagination and the understanding, combined, cannot get forward to that ultimate unity in which they rest in the case of the unitiate unity in which they rest in the case of the Beautiful, and are yet, nevertheless, allured on to make the attempt, but always break down among the endless varieties which such objects are apt to involve, such an object is designated picturesque. And it is to be remarked, that it is generally those minds who have a greater love for variety than unity that love the picturesque. They are rather men of a postical than of a signifific temperature that delicated who have a greater love for variety than unity that love the picturesque. They are rather men of a poetical than of a scientific temperament, who delight as curious old bridges, in old gnarled trees, in ruined towers, and in quaint buildings. Such is an outline of the most complete theory we have of the Beautiful, &c., not entirely unobjectionable, yet more so than any one else. The following is a rapid view of the various theories which have been propounded on the subject by men of distinction in their various walks. St. Augustine, who wrote an express treatise on the the subject of men of distinction in their various wans, St. Augustine, who wrote an express treatise on the Beautiful, which is now lost, distinguished this quality from the useful, and ascribed it mainly to the intellectual unity given to objects by the mind. Crouzas, who cut up Pope's "Essay on Man," and at whom Pope sneered in turn in his "Dunciad," held that it depended sneered in turn in ms." Dumbian, ment ame it appeared on the five elements of variety, unity, regularity, order, and proportion. Pers Andlé accepted these elements, but distinguished them into essential, natural, and 239

artificial. Lord Shaftesbury, author of the "Characteristics," ascribed this feeling to an internal sense, while Hutcheson, of Glasgow, who followed Shaftesbury closely, said nearly the same thing. Dr. Gerard, of Aberdeen, said it depended on a natural variety and uniformity, to which Dr. Reid added the quality of novelty. Burke, who wrote a special treatise on the subject, said that all objects appear beautiful that have the power of producing a peruiar relaxation of our nerves and fibres, and thus inducing a certain degree of hodily language and sinking. Diderot, of the Escaof bodily languor and sinking. Diderot, of the Ever-clopedie, said that it arose from the idea of relation, and the beauty of an object was in proportion to the number and the clearness of the relations suggested or perceived. Père Buffier held that it consisted in mediocrity or conformity to that which was most usual. Alison, in his book on Taste, made all beauty depend on association; and Lord Jeffrey followed in his wake. Payne Knight modified this doctrine considerably by Payne Knight modified this doctrine considerably by introducing the primitive and natural beauty of colours, sounds, &c. Kant ascribes it wholly to the judgment; and Cousin ascribed it to the reason acting under the forms of unity and variety. Dr. Thomas Brown said that it was pleasing as an emotion, and that it was always identified with the object that excited it. Thus we have nearly every possible form of this doctrine maintained by men of eminence. Some say that it is a judgment, others make it a feeling; some say that the longer wholly to the mind thinking, others that it belongs wholly to the mind thinking, others that it belongs wholly to the object thought about; some make

belongs wholly to the object thought about; some make it simple, while others make it complex; some aver that it is original, while others declare that it is derived. The theory of the Pleasurable, briefly described in this article, is the only one we know which vindicates its own truthfulness by explaining the phenomenon.

Brayen, bee-ner, that part of the complete helmet forming the lower part of the front-piece, which, with the avantaille, completed the vizor. When the avantaille was raised and the beaver lowered, the whole face was uncovered; when arranged in the contrary manner, the face was completely guarded. The avantaille covered the face from the chiu upwards till it met the nose; the beaver from the chiu upwards till it met the avantaille. Either could be opened independently of the other. When it was desirable to obtain a freer circulation of air, to eat or drink, while preserving the incognito, the beaver was lowered, as most accurately described by Sir Walter Scott, when Ivanhoe, in the Sir Brian de Bois Guilbert, calls for a bowl of wine, and quaffs it to the confusion of all foreign tyrants. When a knight wished, by disclosing his features, to make himself known, he raised the avantaille of his

BRAYER (Castor Fiber), a rodent animal easily dis-tinguished from the reat of the order by its peculiar tail, which is of a nearly oval form, horizontally flattened. The usual length of this animal is about three feet, exclusive of its caudal appendage. In colonr, the beaver is reddish brown, sometimes deepening into the heaver is reddish-brown, sometimes deepening into black; the hair is of a glossy and smooth nature. The hind-feet are webbed, and adapted to the element in which the animal usually lives. The incisor teeth are remarkably hard and sharp, and act like a chisel. According to Sir John Richardson, the Indians always used these teeth to cut bone and other substances, until the introduction of iron caused their disuse. The same authority says, "When the beaver cuts down a tree, it gnaws it all round, entting it, however, somewhat higher on the one side than the other; by which the direction of its fall is determined. The atumo is the direction of its fall is determined. The stump is conical, and of such a beight as a beaver, sitting on his hind-quarters, could make. The largest tree I observed cut down by them was about the thickness of a man's thigh, that is, six or seven mehes in diameter; but Mr. Graham says that he has seen them out down a tree which was ten inches in diameter." The sagacity and industry of the beaverhave been the favourite theme of naturalists from the time of Buffon to the present day. As food the beaver chiefly profers the bark of trees and such shrubs as the willow, poplar, and birch. It will eat berries in the summer. It hays up stores of food for the winter in the same manner as other rodents. This winter supply mainly coneists of the hard and the same for the same manner as other rodents. bark and branches of trees. The northern part of

Bed

NorthAmerica is the great breeding-place of the beaver, and it is there found in considerable numbers. Some thousands of their skins are annually imported into this country. When the beavers are numerous, they are found to inhabit lakes, ponds, and rivers, as well as those narrow creeks which connect the numerous lakes with which North America abounds; but the two latter are chosen by them when the depth of water and other are chosen by them when the depth of water and other circumstances are suitable, as they have then the advantage of a current to convey wood and other necessaries to their habitations, and because, in general, they are more difficult to be taken than those that are built in standing water. The materials made use of are driftwood, green willows, birch, and poplars, if they can be got; also mud and stones intermixed in auch a manner as must evidently contribute to the strength of the dam; but there is no other care or method observed in constructing the dams, except that the work is carried on with a regular sweep, and the work is carried on with a regular sweep, and all the parts made of equal strength. The boaver-houses are built of the same materials as their dams, and are always proportioned in size to the number of inhabitants, which seldom exceeds four old and six or eight young ones. Instead of order or regulation being observed in rearing their houses, they are of a much ruder construction than their dams; for, not-withstanding the sagacity of these animals, it has never been observed that they aim at any other convenience in their houses than to have a dry place to lie on; and there they usually eat their victuals, which they occasionally take out of the water. So far are beavers from driving stakes into the ground when building their houses, that they lay most of the wood crosswise and nearly horizontal, and without any other order than that of leaving a hollow or cavity in the middle. When any unnecessary branches project inward, they cut them off with their teeth, and throw them in among the rest, to prevent the mud from falling through the roof. It is a mistaken notion to suppose that the woodwork is first completed and then plastered; for the whole of their houses, as well as their dams, are, from the foundation, one mass of mud and wood, mixed with stones if they can be pro-cured. The mud is always taken from the edge of the bank, or the bottom of the creek or pond, near the bank, or the bottom of the crock or pond, near the door of the house; and though their fore-paws are so small, yet it is held close up between them, under their throat. Thus they carry both mud and stones; while they always drag the wood with their teeth. All this work is executed in the night; and they are so expeditious, that in the course of one night they will collect tious, that in the course of one night they will collect as much as amounts to some thousands of their little handfuls. As they are frequently seen to walk over their work, and sometimes to give a flap with their tail, particularly when plunging into the water, this has, without doubt, given rise to the vulgar opinion that they use their tails as a trowel, with which they plaster their houses; whereas that flapping of the tail is no more than a habit, which they always preserve, even when they become tame and domesticated, and more

BEAVER-TEER. (See MAGNOLIA.) BERYUR-TREE. (See MAGNGIA.)
BEBRERU, or BEBREU. (See NECTANDRA.)
BEBRERU, or BEBRERINE, be-be-rise, in Chem., the
term applied by Dr. Rodie, of Demorstra, to as alkali
extracted by him from the bark of the bebeera-tree.
Von Planta and Messrs. Madagan and Tilley have
determined its true formula, which is CPMPRIOC.
Its characteristics are that of a highly fibrage and

hitter substance.

BRCALM, be kam' (Du, kalm), in Mar., a term used to denote the position of a ship at sea when there is no wind stirring, or when the current is intercupted by some object so as to render the ship's sails useless. In this state she lies like a log in the water, because, having nothing to propel her, she can move neither forwards nor backwards. One of the great advantages of a steam-vessel is that she cannot be becalined; for if there be no wind to fill her sails, she can always be

worked by her engines.

worked by her engines.

BECCAFIGO, or BECCAFICO, bek-ka-fee'-ka (Ital., the fig-pecker), the Sylvia hortensis, is a migratory songbird, which feeds upon insects, figs, currants, and other fruits. It is a migratory bird with a very short body, very nearly the size of a linnet. During the summer it is a visitor to England, and even Scotland; but it always departs for a southern climate in Sepbut it always departs for a southern climate in September. Its voice resembles that of a nightingale; it lurks shyly in the thickest foliage, whence its pieceing notes issue, though the tipy warbler is seldom seen, and flies with singular grace. With the ancient Romans it was a highly-prized morsel, and in our own day it is one of the rarest autumnal delicacies of the Italians, the Greeks, and the French. It is especially well prepared in Venice, where, in autumn, when the flesh is most delicate, it fetches in the market four shillings at the lowest price, and often commands as high a sum is most delicate, it letches in the market lour shillings at the lowest price, and often commands as high a sum as one pound spiece. The Italians have an annual feast which they term Beccafficats. The term beccaffic applied rather indiscriminately to different kinds of the Sylviida, or Warblers, when they are fat enough to serve at table.

BECK, bek (Ang.-Sax.), denotes a brook or small atream of water issuing from some spring or rill. It enters into the composition of the names of many English places; as, Walbeck, Bournbeck, &c. The German word back has the same signification, and in like manner forms part of the names of various places;

as, Griesbach.

Bro, bed (Ang.-Sax.), an article of furniture upon which to recline for repose or sleep. In the early ages it was the practice of mankind to stretch themselves upon the skins of animals, which was the custom of the Greeks the Romans, and of the ancient Britons before the Reman invasion; after which event the skine spread for this purpose on the floor of the apartments were changed for heath and rushes; and, in the course of time, the introduction of agriculture applied the central Britons with the greater corvenience of straw beds. The beds at the inns of this period were filled with the soft down of reeds, and those of the Roman patricians with feathers. For many ages the heds of the Italians had been composed of straw; and from them it is probable our country-men learnt its application. In Wales the beds of the humbler classes were stuffed with rushes as late as it o end of the 12th century, and atraw was used in the royal chambers of England at the close of the 18th. Reds appear to have been the chief domestic glories in England during the 14th century, and were considered of sufficient importance to be named in the wills of our sovereigns and the chief nobility. Anne, countess of Pembroke, for instance, in 1367, gave to her daughter a bed, "with the furniture of her father's arms." In 1368, Lord Ferrers left to his son his "green bed with his arms thereon;" and to his daughter his "white bed, and all the furniture, with the arms of Ferrers and Ufford thereon." Edward the Black Prince bequeathed to his confessor, Sir Robert de Walsham, large bed of red camora, with his arms embroidered at each corner; while to another friend he left another bed of camora, enriched and powered with blue eagles; and, in 1385, his widow gave "to my dear son, the king, my new bed of red velvet, embroidered with ostrich feathers of silver, and heads of leopards of gold." In many parts of the country agricul-

Richardson.

particularly so when they are startled. The beaver is found in Europe as well as America, although differing

in one important respect, viz., in the building of its house. Until very recently, it was supposed that the European species did not build its habitation like the

American beaver, but burrowed along the banks of rivers. It is, however, now known that the American

beaver living near the settlements acts in precisely the

same manner as its European brethren, and, moreover, that in certain places which are secluded, the latter build their houses after the fashion of their transat-

lantic friends. At some remote period beavers are supposed to have been common in Scotland; and tradi-

tion implies that Beverley, in Yorkshire, took its name from the circumstance of beavers abounding in the neighbouring river Hull. Giraldus Cambrensis briefly alludes to the Welsh beaver in the 12th century. In-

deed, considering all the evidence, traditionary and recorded, there is little doubt that the beaver at one time was common in Britain. Even in America, where it is so abundant, such is the demaed for beaver skins, that it is very probable that the writer who may record

tural labourers now sleep on chaff beds; and in the Highlands heath is very commonly employed. In Italy and France straw beds are still in general use. The medern bed is a case or sack of ticking, filled with chaff, wool, feathers, or any other soft material, and placed upon a raised wooden or iron framework, which is called the bedstead.

BED, in Geol., the term usually applied to a stratum of considerable thickness, and of uniform homogeneous texture; as in such expressions as "bed of sandstone," bed of clay," &c. Originally, however, the term bed referred to the surface-junction of two different strata. Ban, in Mining, a term applied to an horizontal layer

of ore, stone, clay, &c., of considerable thickness.

BED, DINING (in Antiq., lectus tricliniaris or discr bitorius), a couch running round three sides of a table, for reclining upon at meals, in use among the Greeks and Romans. These dining-couches or beds were four and Romans. I ness uning-countes or beas were four or five feet high, and three of them were ordinarily placed against a square table, in such a manuer that one of the sides of the table remained open and accesssible to the waiters. Among the Romans, the usual number occupying each couch was three; so that the three couches of a triclinium afforded accommodation for a party of nine. It was the rule of Varro that the number of guests ought not to be less than that of the Graces, nor to exceed that of the Muses; sometimes, however, as many as four lay on the couch. Among the Greeks it was usual for only two persons to recline

on each couch.

BED OF JUSTICE (Fr. lit de justice) is, literally, the seat or throne occupied by the French monarch when he attended the deliberations of parliament. Historically, it denotes a solemn proceeding resorted to the wortes by the monarch, in order to carry some measure against the will of the parliament. If any royal decree was opposed by the parliament and the king insisted upon carrying it, he proceeded to hold a lit de justice, i. e. went to parliament in person, attended by the chief officers of his court, and there, mounting the throne (lit), caused the decrees to be registered in his presence; and decrees so registered were considered of greater authority than decisions of parliament. The last bed of justice was held by Louis XVI. at Versailles, Sept. 20th, 1787, at the commencement of the French revolution, in order to enforce upon parliament the adoption of certain obnoxious taxes.

BEDCHAMBER, LORDS OF THE, are officers of the royal household under the groom of the stole. are usually twelve in number, and wait a week each in turn upon the sovereign. The groom of the stole an turn upon the sovereign. The groom of the stole only attends his majesty on state occasions. There are, also, thirteen grooms of the bedchamber, who likewise wait in turn. During the reign of a queen, all these offices are held by ladies. The appointments are in the rôyal nomination, and they all have salaries attached to them. At present [1862] her Majesty has eight ladies of the bedchamber, and three extra: and with the dchamber wowen and one arter. In 1870 Size eight bedchamber women, and one extra. In 1839 Sir Robert Peel, on forming a new ministry, made the un-usual request to be permitted to change the ladies of the bedchamber, a request which he said circomstances justified. This being declined, he resigned his pre-

BEDE-HOUSE, beed house (Sax. bede, a prayer), was a name given to an hospital or almshouse, from the poor people who enjoyed the benefit of them being expected to pray for their benefactors. Hence, a bede-man was one who lived in a hede house, or was supported

by the funds appropriated for that purpose.

BEDERMAN, or BEDEMAN. (See BRADSMAN, and
BEDE-HOUSE.)

REDLAM, bed'-lam, a corruption of Bethlohem, the name of a religious house in St. George's Fields, London, which, after the dissolution of the religious houses by Henry VIII., was converted into an hospital for lunatics, but still retained its former name. In 1675 the old building was taken down, and a new one erected in Moorfields, at the cost of nearly £17,000. In 1814 this second hospital was taken down, and the patients transferred to a new and more commodious building, erected in St. George's Fields having accommodation for 193 patients; and in 1836 a new wing was added to it, capable of accommodating 186 additional patients. The whole buildings now cover, it is said, 14 acros.

BEDLAN BROGARS. — Great improvements have taken place during late years in the treatment of the insune at Bedlam or Bethlehem Hospital. Forthe insune at Bedlam or Bethiehem Hospital. som-merly a cure was seldom effected, and now more than half the inmates are sent out cured. It was also the custom in former years to exhibit the patients publicly in cages, like wild beasts. The funds of the hospital were very small, and many of the patients only partially cured were sent out with badges of tin on partially current were sent out with dadges of am on their arms, with an inscription explaining their state. These wretched beings went about seeking charity, and were called Bedlam-beggars, or Tom-o-Bedlams. Is King Lear, Edgar, as poor Tom, simulates before the blind monarch that he is a Bedlam beggar. They were put a stop to in 1675, when an order appeared in the

put a stop to in 1015, when an order appeared an one London Graette, cautioning the public not to give alms to persons pretending to be Bedlam beggars.

BEDOUINS, or BEDOWERNS, bed-oo-ins (Arab., in-habitants of the desert), a numerous Mahometar race which dwells in the desert of Arabis, Egypt, and Northern Africa. It is still doubtful whether they belong to the same race as the Arabs or differ from them in their descent, as they do in their manner of living. The Bedouins live at a distance from cities and villages, in families under sheiks, or in tribes under emirs. Their dwellings are huts, tents, ruins, and caverns. With their herds and their beasts of and caverns. With their herds and their beasts of burden, which carry what little property they possess, they wander in search of fresh water and pasture. They are good horsomen, and generally fond of hunting. The peaceful tribes exchange horses and fat cattle for arms and cloth with neighbouring nations. Other hordes are open robbers; and it is dangerous to travel through their country without a guard or a pussport, which the different objects sell. Terrible encounters have been the consequence of travellers counters have been the consequence of revenues, refueing to part with their property without resistance. Notwithstanding this, even the predatory Bedouins hold the rights of hospitality sacred; and the most defenceless enemy is sure of their protection if they have once allowed him shelter. But the Ledouin considers every one his enemy who is not his brother, kinsman, or ally. Ever careful of his own esfety, he attacks no camp or caravan without being sure of his superiority.
To a determined resistance he yields, and saves himself by speedy flight. A terror to the neighbouring nations, the rapacious Bedouin lives in a state of con-tinual watchfulness,—poor, ignorant, wild, rude, but free and proud of his liberty. He is remarkable for a temperance in food amounting almost to abstinence.

BED-STREW. (See GALIUM).
BEB, be (Ang.-Sax.).—Under this name, in England alone, are included about 250 species of insects of the ord. Hymenoptera. They are divided into two large groups,—the Andrenida and the Apida. The species of Andrenida are very extensive, and most abundant in the spring. The iemales construct their nests underground in a singular manner. Usually selecting a sandy situation, they burrow in the ground to the depth of about eight or nine inches. This hole, which the Andrenida and the Apida. The species of is cylindrical, is only of sufficient dimensions to admit the bee. The bottom, with the aid of some glutinous substance, is made tolerably smooth. This labour accomplished,—and, considering the soil is only removed a grain at a time, it is no small labour,—it sets forth in search of pollen. This the bee procures from sourch in scarch of poncer. Into the dee procures from flowers, and carries to her cell on her hind legs, which are thickly covered with long hairs. With the addition of a little honey, the pollen is made into a small paste-ball, in which the egg is deposited, and the mouth of the cell hermetically scaled. In time the care becomes a lura and devuise the audiant which egg becomes a larva, and devours the pollen in which it has been enveloped; the larva turns to a pupa, and then the next transformation produces a bec. It, however, remains in a torpid state till the next year. The Apide are a more important group; and the habits of the species belonging to it are more variable than the Andrenide. To this group belongs the bire or honey-bee, which demands particular attention. In the earliest records may be found notices of this insect. Kenophon, who lived more than 2,000 years ago, and who is famous for his remarkably clear and perspicuous with the injury his men received by eating honey of bees which had fed on deleterious plants. Both Aris-

941

tothe and Virgil were observers of its habits. Pliny teils us that the philosopher Aristomachus spent fifty-eight years in investigating bee-nature; and Philisous devoted the whole of his life to this branch of study. Indeed, from the time of the earliest philosophers down to the age of the pious Dr. Watts, it has been a favourite theme. The principal modern labourers in this field of science are Swemmerdam, Résumur, Bonnet, Schirach, Thorley, Hunter, and lastly, and greater than all, the blind naturalist Francis Huber (1750 to 1831). The patient and ingenious investigations of Huber were the means of bringing some most important evidence on the nature and habits of the bee before the world, which had hitherto been involved in considerable obscurity. But the subject is far from exhausted; and although it has engaged the attention of numerous men of science since Huber's time, it is still at the present time (1832) a subject on which the rays of science, guided by the hand of some future skillul explorer, may throw considerable light. Let us, however, bet thankful to those men who have devoted their whole

lives to the investiga-tion of so humble a particle of animated nature, and take a brief and rapid survey of the result of their labours. A beehive contains three classes of inhabitants, - the workingbees, the drones, and the third order, represented by only one member, — the queen-bee. The first class is tho most important. They are believed to be undeveloped females; consequently, incapable of taking part in the reproduction of their species. The species. drones are the males, and exist but for the propagation of their kind. The queen-bee is the mother-bes of the whole colony, and lays about 200 eggs a day through the whole season, from early spring to September. The anatomy of the work-

ing-bee forms one of the most interesting portions of entomology. Its body is about half an inch in of entomology. Its body is about half an inch in length, of a blackish-brown hue, and is covered with rengen, or a placement-rown mae, and is covered with thick hairs, which serve the insect for the purpose of collecting pollen. The most singular part of the body is that which is called the proboscie. This instrument, if casually observed, appears to be a single tail, and formerly it was considered so to be by naturalists. Examined through the microscope, however, it appears a slender projection composed of some forty cartilaginous rings, fringed with fine hairs. It is formed of five parts, a central stalk, and four lateral ones,-two on The central part, used for collecting honey, is aided by the fringed hairs lapping up, like a tongue, enything to which the proboscis is applied, and then conveyed to the pharynx, or honey-bag, whence, in due time, it is disgorged into the cells of the comb. The structure of the other portions of the mouth are beautifully adapted to their several uses. The bee has three pairs of legs, the anterior ones being the shortest, and the posterior the longest. The latter have a cup-The latter have a cuplike cavity on the fore-leg, which the bee uses to con-tain the pollen it collects. The legs are all covered with hairs, and more particularly the ones which carry the pollen. There is a pair of hooks attached to each foot, which enable the bee to walk on the roof of the It was clearly demonstrated by Huber that re spiration was as essential to the boe's existence as that of any warm-blooded animal, Situated behind the wings are spiracles, or air-openings, which admit air for the purpose of oxygenating the circulating system.

That these spirucles were the instruments of respira-

tion, Hober proved by immersing a bee in water; so long as the air-openings were free, the insect fived; immediately they were placed under water, the bubbles which encaped from them proved their use, and the bee ceased to exist. The abdomen contains the honey-bag, the stomach, the wax-bag, the venom-bag, and the sting. The honey-bag, though conssionally called the first stomach, is not used for the purpose of digestion; it is a small bag, shout the size of a pea, with two pouches behind, and is properly only an enlargement of the guillet. This recentacle receives the honey from of the gullet. This receptacle receives the honey from the proboscis, as already stated. A small passage thence leads to the stomach, which receives and digests the food of the bee. It was formerly supposed that the wax of the bee was the pollen elaborated in the standard and afterwards allowed by the mouth stomach, and afterwards ejected by the mouth. The celebrated anatomist John Hunter discovered two small ponches in the lower part of the abdomen; and it was found that the wax is derived from the eaccharing matter consumed by the bee, and that it is accreted from vessels on the surface of these pouches. After the from vessels on the surface of these potentials wax has remained there for a time, it appears externally in scales, usually eight in number, below the medial rings of the abdomen, and is removed by the beet itself or one of its fellows. One of the most important and beautifully developed organs is the sting, which hes close to the abdomen. Viewed through the micrones close to the abdomen. Viewed arrough the merce scope, it presents one of the most elaborate and exquisitely defined pieces of mechanism to be found in the wondrous workshop of Nature. It consists of two long darts, adhering longitudinally, and protected and encased by one sheath. The fineness of this apparatus may be shown by the fact that the sheath itself, which is not nearly so sharp as the durts, placed under a is not nearly so sharp as the darts, placed under a magnifying lens exagerating its proportious some two hundred fold, is, towards the point, quite invisible. We have a subject to the sheath is first protracted and inserted; then the two fine darts follow, and are also inserted. The puncture being made, the poison is conducted in a groove to the end of the sheath. And now the most singular part of the basis of the contraction of the sheath. ness follows. The long darts are armed with nine or ten barbs at the end, and this prevents them from being too quickly withdrawn. Immediately the poison flows in, the darts are withdrawn, and the deadly liquid has a cavity to enter, which soon festers, and produces death. The nature of the poison is not known; it possesses, however, a certain acidity, which will redden regetable blues. With regard to the other senses of the bee, the evidence is far from satisfactory. It has five eyes in all,—three on the top of the head, and two in front. Springing from between the latter are two tubes, curving outwards on each side: these are called the antenna, and serve the insect for the ordinary purposes of vision. The antenna are extremely sensitive, and, indeed, the most useful organs of the bee. By their aid it builds its cells, feeds the young, and stores the hive. They are also used as a medium of recognition with its kind. The combs of a bechive comprise a congeries of hexagonal cells, built by the bers as a receptacle for honey and for the nur-series of their young. Each comb in a hive is com-posed of two ranges of cells backed against each other: the base, or partition, between the double row is so disposed as to form a pyramidal cavity at the bottom of each. There is a continued series of these double combs in every well-filled hive, the spaces between them being just sufficient to allow two bees, one on the them being just sufficient to allow two bees, one on the surface of each comb, to pass without touching. Kach cell is hexagonal, the six sides being perfectly equal. This figure insures the greatest possible economy of material and space. The outer edges of the cells are slightly thickened, in order to gain strength. The same part is also covered with a beautiful varnish, which is supposed to give additional strength. Tho construction of several combs is generally going on st the same time. No sooner is the foundation of one laid, with a few rows of cells attached to it, than a second and a third are founded on each side, parallel second and a third are founded on each side, parallel with the first; and so on, till the hive is filled, the combs which were commonced first being always in the most attranced state, and, therefore, the first com-pleted. The design of every comb is sketched out, and the first radiments laid, by a single bee. This foundress bee forms a block out of a rough mass of war,

## Beehive

own woods. The qualified property which may be thus held in bees continues while the swarm remains on the held in bees continues while the swarm remains on the soil, and, in the event of flight, so long as the namer can pursue it. Indeed, so clearly are they considered, in law, of the nature of property, that it has been decided in England that bees may be the subject of lureeny. According to Scotch law, as propounded by Mr. Erskine, bees who abandon their hive without being observed and followed, are understood to have recovered their original liberty: any one, in such a case, may hive and claim them. In the illustration upon the preceding name are furned. the preceding page are figured:—I. the queen-bee; II. the drone; III. the working-bee. For details of management, see Brentye and Keeping of Bres.).

Brech. (See Facus.)

BEE-EATKE, be-e'-ter (Merops apiaster). - These birds are found in large numbers in the southern and eastern provinces of Europe and the northern districts of Africa. They build their nests in clay and sand of Africa. Th

sociate 60 closely together, that the earth appears like a honey-There comb. is some analogy between these birds and the swallows; indeed, in the neighbourhood of the Cape, where they most abound they are called by the Dutch mountain swal-

BEE-EATER.

house in certain parts of Africa they are much respected by the natives, who have a belief, that by following one of them, the discovery of a store of honey will be the certain result. They are larger than the common swallow, and have a long and slightly-curred beak. Their colour is a blending of white, and brown, and green.

BERF. (Sec FOOD, ANIMAL.)

BERF-RATER, a gen. of birds only found in Africa. This bird belongs to the ord. Insessores, tribe Coniros-They have short bills, swelling towards the point, and square at the base. They subsist upon the larves of gadflies, which they find in the hides of buffaloes, of gadilies, which they find in the mores of buliances, camels, and other large quadrupeds. They perch upon the backs of these animals, and Dr. Livingstone states, with regard to one of the species,—the buffulo-bird, that as their sight is keener than that of the buffulo, they see the approach of danger first. When the buffalo perceives that the birds are flying away, he is warned that he is in peril, and begins to look around

warned that he is in peril, and begins to look around him. The beef-eaters are sometimes called ox-peckers. BEEF-RATERS, beef-e-ter, a name popularly given to the yeomen of the guard. Differences of opinion exist as to the origin of this term; but it is generally derived from the French beffetier, from their waiting at the round table. at the royal table on great occasions. They were first constituted by Henry VII. in 1485, and have continued as a royal institution, and with nearly the same costume,

to the present day.

Brer Tra, beef-te', a light soup or broth made from ox-flesh. In all preparations of soup, the raw meat should be put into cold water, which should be very gradually brought to the boiling point. By this means the juices of the flesh are extracted from the first moment, and, with these, lactic and phosphoric acids, two of the principal components of the gastric juice. The best method of preparing beef tea is to take finelychopped raw beef, as lean as possible, and allow it to soak for ten minutes or more in its own weight of cold water; then heat it gradually to boiling. After boiling

drawn partiy from its own resources, but principally from those of other bees, which farnish war from small sace, in which it has been secreted, that are situated sacs, in which it has been secretical, that are strated between the segments of the body of the bee, taking out the plates of wax with their hind-feet and conveying it with their fore-feet to their mouths, where it is moistened, and rendered soft and duotile. The mass of wax prepared by the assistants is applied by the foundress bee to the roof or bottom of the hive, and thus a slightly double convex mass is formed. When of sufficient size, a cell is sculptured on one side of it of sunctions size, a cell is somptured on one size of it by the bees, who relieve one another in the labour. The sells intended for the drones are considerably larger, and more substantial, than those of the workers, and being formed subsequently, they usually appear nearer the bottom of the comb. Last of all appear nearer ane contom of the confidence in the form are built the royal cells for the queens; these are situated in the very centre of the hive, and number from three to twelve. When the cells are ready, the queen begins to lay her eggs. The fecundation of the queen-bee is very extraordinary. It has been pretty clearly ascertained that no connection takes place with the drones in the hire. The question naturally arises, why this large number of drones in a hive? Huber's investigations have to a certain extent cleared away the mystery. According to this eminent naturalist, fecundation takes place by contact in the air; and it is consequently essential that the number of drones should be large, that the queen-bee may be sure of meeting them when going abroad. One intercourse is suffi-cient to render the queen-bee fruitful for two seasons. It is estimated that she gives birth to 100,000 bees in a single season. The eggs which are to produce working-bees are laid first. These are carefully watched; and, when they are hatched, the larva is fed with mixed honey, pollen, and water, by what are called murse-less, whose whole work is to nurse the young bees. Not until eleven months have elapsed in laying ing-eggs, does the mother-bee commence laying the male and royal eggs. The nursing of the latter is managed on a grand scale. The royal larva disdains simple honey or pollen; it must have rich jelly, and in such quantities that her highness's cell is saturated with it. This waste is rather contradictory of the bee's frugality; but bees are wonderfully loyal creatures. From the egg to her majesty bee, the whole time occupied in the metamorphosis is about sixteen days. Now the bees only require one queen at a time; indeed, most monarchical institutions would find it extremely inconvenient to have more. So these newly-batched majestics must be kept confined until the throne is vacant. There is also another important reason why they are not set at large. When two queen-bees meet, it is certain death to one. At the same time they cannot manage without a queen; and each time a swarm take their de parture, a queen is always at their head. There are generally too many royal bees; hence, when they are brought together, a fight cosues, and the number is diminished. Ferhaps the most singular phenomenon in bee history is the making of a queen. On extraordinary occasions, when the hive by some accident is depriced of a queen, and destitute of royal larva, a wonderful provision is resorted to. One of the working larver is selected, deposited in a royal cell, fed on the same food which is administered to the royal larva, and it ultimately be-comes a queen. The only explanation that can be given is, that the peculiar food provided has the effect given is, that the jecture it too provide has the enter of rendering the honoured insect fertile. Towards the beginning of August, a good stock of eggs having been laid, the drones are no longer required; and winter, long and dreary, is before the industrious bees. What must be done with the lazy ones? They are massacred by the workers. A buzzing commences in the hive; the heavy drones and the nimble workers grapple and hug: but the strength of the lazy drones avails them nothing; the sharp stings of the workers pierce them reching; the sharp stings of the workers pierce them through, and presently the ground is heaped with the sola for ten minutes or more in its own weight of cold water; then heat it gradually to boiling. After boiling nesects are, according to Blackstone, wild by nature; but, when hired and properly reclaimed, are regarded in the nature of property, belonging to the person on whose ground or soil they have swarmed. In support both shortine, Blackstone erefers to the Charter of this doctrine, Blackstone erefers to the Charter of the Forest, 9 Henry III. c. 13, which allows every freeman to be entitled to the honey found within his term applied to the habitation of bocs. They are 213

#### Boshive-House

usually made of straw or wood. The former substance is most common, as the honey is liable to mak in wooden hives during hot weather. Glass hives, or hives with glass doors or windows, so as to observe the motions of the bees, are now much used, and in Greece and Turkey the hives are principally made of earthenwere. The shape of a beehive is not of much earthenware. The shape of a beehive is not of much consequence, but it is considered of importance to have the hive so constructed as to be enlarged above or below at pleasure. Beehives should always be situated in the neighbourhood of flowers. Honey made from heather-flowers is much esteemed in Scotland; and when the season of the heather-bloom comes on, a large number of hives are removed to the moors and s. In Egypt hives are removed from place to place on the Nile in barges, in order to reach the places where particular flowers are in season. Bechives are usually about eighteen inches above the ground, and are generally protected with a shed or straw hood, to protect the bees from the rain.

BERRIVE-HOUSE, a term employed to distinguish small, round, stone buts which are found in Ireland. They are very rudely built, and are supposed to be the relies of the most ancient architecture of the island. The doors have flat tops, and are wider down below than above, as in the buildings of Egypt. When a beehive-house is found alone, it is mostly near the site of an ancient oratory. This favours the notion that they were the dwellings of the priests. When two or three beehive-houses are clustered together, they are usually connected by a passage, and are often under-ground, resembling the Picts' houses or earth buts found on the north-east coast of Britain. Ruins of beehive-houses exist in the western islands of Scotland.

BEEMASTER, one who keeps bees. (See KEEPING OF BRES.)

BERR. (See ALE, BREWING, PORTER.)

BERR. (NEGALE, DREWING, COLLEGE,)
BERRACTS. (See Alemouses.)
BERRACTS. (See Alemouse.—In the year 1800, the
BERRACTS to the English military authorities
to add one penny per day to the pay of the British
troops while on home service, in lieu of the heer and spirits which had formerly been issued. This allowance received the name of "beer-money;" and to this day it figures as a distinct item in the military accounts.

BRESHA, be'-sha, in Bot., a gen. of grasses nearly allied to the Bamboo, but differing from it in having the seed inclosed in a fleshy pericarp. Two species are known, both natives of the East Indies.

BEESWAX, bees' max. — This substance has been investigated by numerous chemists. It appears, from the researches of Brodie, that wax is a true animal secretion; for bees fed on sugar only, continue to desecretion; for bees ted on sugar only, continue to de-posit it in large quantities. At ordinary temperatures, beeswax is a tough solid yellow substance, having a specific gravity of 0.96, and fusing at about 145°. When exposed to the air in thin slices, it becomes bleached; but nitric acid is generally employed for this purpose. Chlorine cannot be used for this purpose, as it is climinated in suffocating fumes of bydrochloric acid when the wax is burned. Wax consists chemically of rayricine, insoluble in boiling alcohol; cerine, a crystalline substance dissolved by boiling alcohol; and cere-leine, which is dissolved in cold alcohol. Wax is imported in large quantities from Germany, Russia, Portugal Zanzibar, East and West Indies, and North America. The wax from these countries bleaches readily; while that from Gambia, Cuba, and the Gaboon, seldom reaches a good colour; notwithstanding which, the major portion of wax imported into England comes from the first-named locality. The process for bleaching wax is simple but tedious. The wax is cut in The process for pieces, meited, and agitated with a small portion of very dilute sulphuric soid, which facilitates the separation of impurities. When perfectly clean and bright, it is sliced by a cutting-machine into very thin shocts, and exposed to light and air for eight or ten weeks, during which time it is remelted once or twice. (See CANDLES, VEGRTABLE WAX.)

# Beggar

pearance. It is a dipterous or two-winged insect, and pearance. It is a dipterous or two-wingen inserts and belongs to a genus whose larvar inlest and feed upon the roots of cabbages, turnips, &c. (See Carrage Bly, Turnips-Fly, Potato-Fly.)
Bertin, bed-tl.—This term is frequently used to designate the large tribe of inserts called Scarnobisides,

but it is more frequently and correctly used as the name of those insee. which are covered with a strong horny substance, and have the abdominal part of the body guarded by two sheaths, under which the wings are folded. Hence the word is often used in works on natural history as the ordinary designation for colcopterous insects. This, however, is not correct, as it would bring under the title of Beetle, cantharides, weevils, fire-flies, &c. (See the articles Coleoptera, Scarabæides, Stag-Beetle, Tiger-Beetle, Bom-Bardier-Beetle, Burving-Beetle, Goliath-Bee-

TLE, ROSE-BEETLE, &c.

BEETLE-STONES.—In a cliff composed of shale, at
Newhaven, as well as upon the beach in the vicinity, there are found certain indurated nodules of clay iron-These minerals are selected by the lapidaries of Edinburgh to be fashioned into articles of ornament; as, letter-weights, &c. When highly polished, these stones present a very attractive appearance. The term is said to have owed its origin to a fancied resemblance of the nodules to a fossil beetle. Although some of these minerals exhibit proofs of an animal origin,—a fossil fish, for instance, the nucleus of the nodules is never that of a fossil beetle.

BEETLING, a process applied to cotton shirting, in which the yarn is so treated as to give the cloth a hard appearance, in imitation of linen. a hard appearance, in imitation of linen. It was first employed upon linen shirting. A number of wooden empayed upon men surring. A number of wooden stampers, placed in a row, strike upon the cloth as it passes under them, producing the effect required. The engravings given at figs. 1, 2, and 3, on the next and fol-lowing pages, represent an improved form of machine for the production of ornamental or other figured fabrics by pressure from corrugated or indented surface-rollers of various patterns. The improvement consists in the peculiar construction and arrangement of suitable machinery for giving to woven fabrics a glossy fluish similar to that which is now produced by the ordinary stamps in the machines called beetles. This invention This invention also relates to improvements in arranging or applying steam or fluids to such purposes, thereby giving a certain pressure to the rollers employed in the improved beetle, as also for a combination of mechanical arrangements necessary for the construction of a rollermangle, with sufficient to produce the operation of beetling. The engravings on the next page represent a front elevation and an end elevation of this machine, with the same letters of reference applying to similar parts. A A are cast-iron stand and frames, having side-claw projecting hearings, B B, with two central horn-shaped ones, A carrying the pressure-lever links; C C are bush-bearings for the journals of the beetling rollers D and E, which rotate horizontally with each other in opposite directions; FF is the roller upon which the cotton fabrics about to undergo the beetling process are wound; GG is the pressure-roller mounted in the lever-link motion-head HH, upon the central horn-standard j, in a manner subsequently explained; I is the shaft upon which the pressure-roller revolves; K K, two connecting-rods on each side of the machine, attached in vertical positions at the top to the links H H, and at their lower ends to the weighted levers L L; M is the centre stud upon which the levers L L radiate; N N are two spherical-shaped halls or weights for giving pressure to the roller G, through the medium of the levers L L, assisted by their own gravity. O is the horizon or which the comments. gravity; O is the bearing on which the connecting-rods K K move; P is an intermediate crank motion-rod coupling the two way link-shafts V R, and giving motion horizontally to the horizontal rest-bars T T through the quarter-way links 5 S, in year with the same; U U are two sour-wheels mounted upon the beetling roller-shafts D and E, in gear with a pinion V, on the driving-shaft; WX is a long hand-lever, the CANDLES, VEGETABLE WAX.)

BERT. (See Beta.)

Bert. (Authornia Beta), an insect not so object of which is to raise the different roners from their beds by it in the manner hereafter explained. leaves of beetroot or mangel-worzel. When the Having thus far described the various arrangements harm leave the eggs, they devour the soft parts of the same parts of which this invention consists, it is necessary to explain its mode of working, and the numerous 244

# Beetling

advantages that may result from its application to the various purposes for which it is intended. Steam or other motive power is in the usual manner first applied to the driving-shaft W, which is mounted in a bracket bearing against the standard-draming, as represented in the engraving; whilst the other end is similarly mounted against a wall or other convenient place, and when driven by the action of steam, it causes the

## Beetling

rollers, it is then passed between the beefling-rollers D and E, which are furnished with peripheries such as are seen in the two engravings on the next pages; these are embossed or checkered in different patterns, corresponding to the rollers employed. The Isbrius are then taken from the rollers, and replaced by others during the working of the machine, and the operations effected. The pressure to which the fabrics are ex-

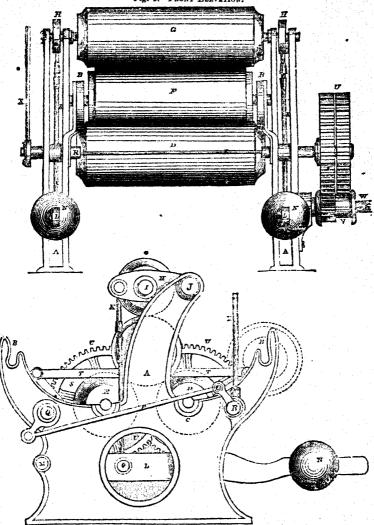

Fig. 2 .- END ELEVATION.

pinion V, on the end which takes into the spur-wheels U U, to propel the same, and thereby give the required motion to the machine or apparatus during the process of beetling. It must be observed that the cotton fabrics about to be mangled or beetled are first wound upon the roller F; to accomplish which, the roller has to be removed or taken out of its place, which is performed in the manner hersafter explained. Having completed the operation of winding the cotton on the

posed by the constant rotation of the rollers between which they pass, is produced and carried into effect as follows:—The roller GG, with its morable link-bearings on each side centred on the horn-shaped standards, are caused, through the medium of the side connecting rods K K, to receive the cutire weight of the levers L L, in addition to the weights H H on the ends, and consequently offer a sustaining pressure to the fabrics during the process of beetling. On the other hand,

when it becomes necessary to supply the apparatus with plain ootton fabrics, and remove those already bestled, the levers L L, which are represented as having holes at one end for the employment of any shitable or convenient tackle, are to be by such means raised, the action of which will have the effect of raising also the head-links and pressure-roller, and thus, by removing the weights, enable the roller bethus, by removing the weights, enable the roller be-neath to be lifted out of its scat and placed in one of the

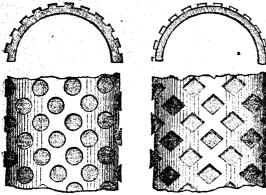

Fig. 3.-BLETLING-MACHINE.

end claw-bearings (BB), as represented by the dotted ders employed in the process of beetling or otherwise. The mode of effecting this part of the operation (See Calendral), will be readily comprehended by reference to fig. 2, BERTROOT SUGAR. (See SUGAR.) where TT shows a bar of iron horizontally placed on each side, beneath the journals of the roller F, forming a rail or table upon which they are to be moved. When a downward motion of the lever handle is given by the operator, it causes the coupling-rod P, through the medium-links P R, in connection with others on the same shaft, in gear with the rest-bar TT, to move upwards horizontally, similar to the action of a parallel rule, and raise the rollers F or B out of, or into, their respective places, by enabling the rollers to be rolled along them when disengaged from their bearings or seats, and carefully lowered into their places, in readiness for the next operation. From these observations it will be seen that, first, the levers L L are to be raised in the manner which will cause the roller GG to be also raised through the medium of the connecting rods K K, when the pressure will be removed from the lower rollers, and which will enable them to be raised to the required height, so as to transfer them from one seat or bearing to another, and thus allow the fabrics to be changed by removing those already having undergone the process, and supplying the other roller with plain ones. The patentee, although he de-scribes and sets forth the employment of the side levers, yet does not confine himself exclusively, as other and equally effectual means may be applied with the same advantages, - such as steam pressure, liquids, or otherwise; and in many cases the weight of the rollers themselves might be found sufficient to give the required pressure, without other intervention. required pressure, without other intervention. The next object to which the patentee directs attention, is to the improved mode of constructing roller-mangles, which consists of very nearly the same arrangement of rollers, the only apparent difference being the introduction of a flexible lever or spring, firmly fixed to the standard upon which the pressure-roller is mounted, being brought to act upon the same to any degree of force by the application of a handwheel and screw-spindle supported in bearings suitably stranged. To the end of the screw-spindle two fixed studs are attached, between which the lower end of the flexible lever or spring is introduced, so that when the spindle is screwed to or from the centre of such the spindle is screwed to or from the centre of such standard carrying the roller, the pressure is applied, by reason of the standard moving from a centre with the roller under an elastic pressure, thus given by the forward or backward application of the screw hand-

The patentee states that cast-iron rollers may be employed for dry articles; but for damp ones, bell-metal would be found better adapted. One of the advantages derived from this system of man-gling, is the small space the machine occupies, together with the accommodation which it offers by being placed within a piece of furniture having drawers for the purpose of disposing of the various articles when so mangled. That which the patentee claims as

new in this invention are,-first, employment of rollers having indented, grooved, checkered, or undulated surfaces or peripheries, for producing by pressure corresponding marks or impressions therewith upon cotton or other fabrics; secondly, for the general arrangement of parts constitution the sction and construction of the said improved machinery; thirdly, for the employment of water or other fluids within the aforesaid rollers, to act independently of other pressure apparatus, such as the long levers shown at L L figs. 2 and 3; also for the application of steam to such purposes, causing, in the usual manner, by its expansion within a cylinder, a pressure to be exerted upon the rollers, and at the same time that such application should be available for the purpose of taking off and removing the pressure when required,—the same means employed for the one being found effectual in performing the other; fourthly and lastly, for the use of the numerous patterns as applied to cylin-

BEFANA, or BEFFANA, he-ful-nd, a corruption of Epiphania (Epiphany), is the name of a custom which prevails in Fiorence and other parts of Italy on Twelfthnight. Befana is said to have been an old woman, who, when the wise men of the East passed by, was busy in cleaning her house, and excused herself from going out to see them, on the ground that she would see them on their return. They, however, went home another way, and she is said to be still on the outlook for them. She is carried in effigy through the streets, amid great shoutings and rejoicings. It is generally supposed to be a remnant of some Middle-Age mystery ceremony. The

word is also used as a bugbear to frighten children. Beperal, or Penery, bef"-freum, a movable tower used in ancient and Medieval sieges. It was as high as the walls of the fortress to be besieged, and was composed of various stages, the highest one being provided with a drawbridge, which could be let down upon the ramparts of the place attacked. Similar towers, but lower in height, were used for covering the approach of troops. They all moved on wheels, the approach of troops. They all moved on wheels, and were either pushed forward or drawn with ropes. They were used by Julius Cresar in Gaul; and at the siege of Jerusalem the Crusaders made a beffroi, put it togother at a short distance from the walls, and then at together at a short distance from the wans, and then pushed it up to the ramparts. A beffroi was also made by the royalists in the time of Charles I., when attacking a fortress held by the roundheads. It was, however, captured, before the king's party could make use of it. In more ancient times, these morable towers were often covered with raw hides, to protect the industrial form the library of the content of the form of the content the inclosed soldiers from the boiling oil, &c.

were often provided with a battering-ram.

BEG, or BEY, bai, is a Turkish title, literally signifying lord or chief, and is applied generally to governors of smaller districts, higher military officers, and other persons of rank.

BEGGAR, bey'-gar, is one who solicits charity. There BEGGAR, beg'-qūr, is one who solicits charity. There must necessarily exist in every country certain persons who have not the means, ability, or, perhaps, the will, to earn a licelihood for themselves, and who are thus dependent for subsistence upon the charity of others. These constitute the poor: when they have to solicit charity, they are beggars. In the Levitical law, Moses made abundant provision for the poor; but he does not appear to say anything with respect to beggars. The first express mention of them occurs

### Beggar

in Psalm cir. 10, and from that time they are frequently mentioned in Scripture. During the time of Christ, mendicants were found sitting in the streets, at the doors of the rich and at the gates of the Temple; but there do not appear to have existed at that time vagrant beggars, or those who solicit alms from door to door. During the early and middle ages of our era, mendicity prevailed to a great extent and several re-ligious orders aprang up who derived their subsistence in this way. There is much in the life of a beggar that renders it to many persons preferable to one of labour; and hence it is necessary for the state to limit or sup-press it. In England, the earliest statute of that kind was made in the 23rd year of Edward III. (1349), and was made in the 20rd year of Edward III. (1989), and it enacted, "That, because many valiant beggars, as long as they may live of begging, do refuse to labour, giving themselves to ideness and vice, and sometimes to theft and other abomination, none, upon pain of imprisonment, shall, under the colour of pity or alms, give anything to such as may labour, or presume to invour them in their sloth; so that thereby they may be compelled to labour for their necessary living." In 1376, complaints are made by the Commons that servants and labourers quitted service on the slightest vants and tabourers quitted service on the signtest cause, and then led an idle life in towns or wandered in parties about the country, "many becoming beg-gars, others staff-strikers, but the greater number taking to robbing;" and by 12 Rich. II. c. 3, it was enacted, "That no servant or labourer, be he man or weman, shall depart, at the end of his term, out of the hundred, rupe, or wapentake where he is dwelling, to serve or dwell elsewhere," without special license; "and if any servant or labourer he found in any city or borough, or elsewhere, wandering without such letter, he shall be taken and put in the stocks, and kept until he hath found surety to return to his service, orto serve and labour in the town from whence he came." The same statute declares that every person that goeth begging, and is able to serve or labour, it shall be done of him as of him that departeth out " of the hundred or other place without letter testimonial, as afore is said;" and "that beggars, impotent to serve, shall abide in the cities and towns where they be dwelling at the time of the proclamation of this statute; and if the people of the cities and towns will not or may not suffice to find them, that then the said beggars shall draw them to other towns within the hundred, rape, or wapentake, or to the towns where they were born, within forty days after the proclama-tion made, and there shall continually abide during their ives." The statute 27 Henry VIII. c. 12, after stating that "vagabonds and beggars have of long time increased, and daily do increase, in great and ex-cessive numbers," enacts that justices of the peace and other officers shall, within the limits of their authority, grant letters to aged, poor, or impotent persons, au-thorizing them to beg within a certain prescribed limit; and if any one be found begging beyond his limit, or without such letter of authority, he shall be set in the stocks or whipped. Able-bodied persons, found begging or vagrant, to be taken to the next market-town, or other place most convenient, and there tied to the end of a cert and heaten with whips throughout the same till the body be bloody; and, after such punishment, "he shall be enjoined, upon his oath, to return forthwith the next straight way to the place where he was born, or where he last dwelled the space of three years, and there put him self to labour like as a true man oweth to do." Five sent to moour me as a crue man owen to do. Trive years later another act was passed, providing that mayors, bailiffs, and other head officers of cities, towns, and parishes, shall most charitably receive and provide for such poor persons or sturdy vagabonds as shall come into their districts, and shall receive a claims and hear the said poor people has succour, relieve, and keep the said poor people by way of voluntary charitable alms in such wise as none of them shall of necessity be compelled to wander and go openly in begging; and also shall cause the said sturdy ragation and valuant beggars to be set and kept to continual labour in such wise as they may get their own living with the continual labour of their own

# Beggar

ing in idleness to be indicted and tried at the next quarter sessions; and, if found guilty, shall be ad-judged to suffer death as a felon. It further provides, judged to suffer desta as a reson. It is that the thirdren above five and under fourteen years of age were to be taught some craft by which they might not their livings when they came of age. Notwithget their livings when they came of age. Notwith-standing these severe enactments, the number of idls beggars and vagabonds seems to have increased; and 1 & 2 Edw. VI. c. 3, after repealing all previous enact-ments, declares that every loitering and idle wanderer-who shall refuse to apply himself to honest labour is to be taken as a vagabond; and if he continue idle, and refuse to labour, or run away from work set him to perform, he is to be brauded with the letter V, and be adjudged a slave for two years to any person who shall demand him, to be fed on bread and water and refuse meat, and caused to work in such labour, how vile however it be, as he shall be put to, by beating, chaining, or otherwise. If he run away within the two years, he is to be branded in the check with the letter B, and adjudged a slave for life; and if he run away. again, he is to suffer death as a felon. sions were made by this statute for impotent beggers and children, similar to those under 27 Henry VIII. The number of vagrants, however, seems still to have increased; and Strype relates, that letters having been issued by the privy council to the sheriffs of the different counties to search for and apprehend "all vagabonds and sturdy beggars commonly called rogues or Egyptians," 13,000 "masterless men" were taken up. In 1566 a book was published, entitled "A Cavest, or Warning for Common Cursetors, vulgarly called Vagabonds," by Thomas Harnan (reprinted 1814), which gives a curious and graphic account of the hordes of idle vagabonds who then infested the country. He classes the male vagabonds under fifteen separate decassive the male vagatoria under filtern separate designations; the female under nine. In the forther case he begins with the "Ruflar," as being "the worthiest of this nevuly rabhlement." "The Upright Man" is the "second in sect of these rainging rabblement of rascals." The third is "the Hooker or Angler," ment of rasculs." The third is "the Hocker or Angler," described as a "perilous and most wicked knave." described as a "perious and most waster anave.

The fourth is a rogue, "neither so stout or hardy as
the upright man." The fifth, a "Wild Rogue," is
"more subtile and more given by nature to all kinds of
knavery than the other." 6."A Prigger of Prauncers," knavery than the other. O. A Frigger of Francers, or Horse-stealer; 7. the Palliards or Clapper-dogens; 8. Fraters; 9. Abraham-men; 10. Fresh water Mariners, whose "ships were drowned in the great plain of Salisbury;" 11. Counterfeit Kranks, who counterfeit the falling sickness; 12. Dommerars; 13. Drunken Tinkers; 14. Swadders, or Pedlars; 15. Jarke-men and Patricios. All of them, both men and women, are described as thieves by profession, and as living most dissolute and licentious lives. They have a sing language of their own, of which the writer gives a specimen in a dialogue between two of them; and he further gives a long list of the most notorious and wicked street-walkers "that are living now at this present, with their true names, as they be called and known by." During the reign of Elizabeth various attempts were made to ameliorate the condition of the poor and suppress vagrancy; and various statutes were passed on the subject. In some of these the notion of a parochial fund for the relief of the poor, and the principle of taxing the parishioners for that purpose, are distinctly recognized. It was seen, that in order to justify severity against vagrancy and mendicity, it was necessary to provide the means of re-lieving that destitution which was the ready and plausible excuse for both, as well as to provide labour for able and sturdy beggars, and to compel them to work. Hence it was enacted, that in every city, town, or other place that may be appointed, a competent stock of wool, hemp, flax, iron, or other stuff, be pro-vided by taxation of the inhabitants, and given out to be wrought by the poor; and that houses of correction be established. The statute 39 Elizabeth, c. 3, provides for the appointment of overseers of the poor in continual labour in such wise as they may get their each parish, who are empowered to raise, weekly or own living with the continual labour of their own hands. For absenting themselves from such labour, they were not only to be again whipped, but to have sum and sums of money as they aball think ft, a continual they were not only to be again whipped, but to have sum and sums of money as they aball think ft, a continual they were not only to be again whipped, but to have sum and sums of money as they aball think ft, a continual they were not only to be again whipped, but to have sum and sums of money as they aball think ft, a continual they were not only to be again whipped, but to have sum and sums of money as they aball think ft, a continual they were not only to be a sum and sums of money as they aball think ft, a continual labour in such was a sum of the said parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, weekly or cache parish, who are empowered to raise, and the parish and

and also competent sums of money for and towards and also competent sums of money for and towards the necessary relief of the lame, impotent, old, blind, and such other among them being poor and not able to work; and also for the putting out of such children to be apprentices, &c. This act was followed by the 43 Elizabeth; c. 2; which is the foundation and text-book of English poor-law, and under the provisions of which all relief of the poor in England and Wales has been entiministered for more than two centuries and a bulf.

all relief of the poor in England and Wales has been administered for more than two centuries and a half. (For an account of this and the subsequent statutes bearing upon the provisions for the poor, see Poon Law.)—Ref. Nicholl's History of the English Poor Law; Blackstone's Commentaries, by Kerr.

BEGGAB MY NEIGHBOUR.—A simple and easy game at cards. The whole pack is dealt out to two players, and the cards are held with the backs upward; each player then turns up a single card in turn. When you play an ace, your adversary must give you four cards; three for a king, two for a queen, and one for a knave; and when the requisite number are laid down, you win three for a king, two for a queen, and one for a knave; and when the requisite number are laid down, you win the trick, and place the cards so won at the bottom of those in your hand. If, however, your opponent turns up an honour while paying for that which you have previously paid, you must pay for it in a similar maner, according to its value, and so on until a complete payment is made on either side. The player who first exhausts his adversary's hand, and gets all the cards into his own, is said to beggar his neighbour.

BECHARDS, beg'-hards, in Eccl. Hist., was a name applied to a certain class of half-monks who followed

applied to a certain class of half-monks who followed the third rule of St. Francis. By some the name is derived from St. Beggs, by others from the old German verb beggen (now begehren), to beg, and hardt or hart, hard, with importunity. They arose in Germany in hard, with importunity. They arose in Germany in the beginning of the 13th century, whence they spread into the Netherlands, France, and Italy, where they were known as Bizochi and Bocasoti. As they belonged to no monastic order, they were regarded as laymen; and, from their irregular mode of life, they were looked upon with disfavour, and subjected to persecution. It formed a kind of refuge for heretics and persons of loose character, so that it came to comprise a number of sects or bodies who differed widely from each other in their opinions, discipline, and mode of life,—some given to prayer, others to prolitage. At length the Beghards were compelled to disperse, or to join the orders of the Dominicans or Franciscans. In the Netherlands, where they preserved a better character,

they continued to subsist longer; but there they dis-spiesred about the end of the lath century.

BrGLERBEG, bai-ler-bai, is a Turkish title, literally signifying prince of princes, or lord of lords, and is applied to the governors-general of provinces who are next in rank to the vizier, and have under them several begs, agas, &c. In particular, the governors of Rou-

neita, Anatolia, and Syria, have this title.

BEGONIA, be-go'-ni-d (so named after Michel Bégon, a French botanist), in Bot., the typical gen. of the nat. ord. Begoniaceæ. The species are natives of tropical regions, but many are now cultivated as ornamental plants throughout Europe. The leaves are oblique or unequal (more developed on one side of the nuidrib thus, or the other), and are offen right throad with than on the other), and are often richly tinged with crimson. The flowers are of a delicate pink colour, and grow in cymes. The young stems and leaves of the species B. malabarica and tuberosa are used as potherbs in the countries where they grow wild. Of the numerous species which adorn our conservatories, B. argyrostigma and discolor are perhaps the most beautiful. The first of these, the siter-spotted begonia, was brought to this country from Brazil in the early part of the present century; the leaves, which are long and pointed, are red beneath and spotted with white above. B. discolor, or two-coloured begonia, is a Chinese species, and is remarkable for the very rich crimson of

species, and is remarkable for the very rich crimson of the under-surface of the leaf, which is short and broad.

BEGONIACEE, be-go-ni-ni-se-e, in Bot., the Begonia fam, a nat. ord. of dicotyledonous plants in the subclass Monochlamydee, consisting of four genera and 100 species, natives chiefly of India, South America, and the West Indies. The species are herbs or low succuleut shrubs, with alternate leaves which are oblique at the base and have large dry stipules. The flowers, which grow in cymes, are unisexual, the perianth coloured, with four unequal divisions in the male flower,

and five or eight in the female. The stamens are numerous; the fruit is membranous, winged, three-celled, bursting by slits at the base; the seeds are very small. The plants are more remarkable for their handsome leaves and neat flowers than for useful properties.

They are reputed, generally, to possess astringent and bitter qualities, and occasionally to be purgatire. Brevins, beg-u-ins, in Eccl. Hist, were s class of women who, without taking any vows or following the rules of any order, united themselves together for devictional or charitable purposes. They appeared in Germany and the Netherlands as early as the 11th century, and we said to hear taken their name from St. Bergard. and are said to have taken their name from St. Begg They lived generally in small separate cottages, under the direction of a superior, and were distinguished from the rest of the laity only by their industry, piety, and secluded habits, and their great attention to the education of the young. They continued to exist in Germany to the time of the Reformation, and in the Netherlands down to the close of the 18th century. There are still to be met with in some parts of Holland, Belgium, and Germany, what are called Beguinen-hänser; but these are little more than almshouses for poor spinsters. The most famous is at Ghent, which is said to comprise 600 inmates, who devote themselves to attendance on the sick and the education of young

BEHEADING. (See DECAPITATION.)
BEHEMOTH, be'-he-moth, an animal of great strength, described in Job zl. 15—24, and nowhere else mentioned in Scripture. Commentators are very much, divided as to what animal is meant. By some it is understood to be the elephant, by others the hippopotamus; the general opinion seems to be in favour of the latter

BEHMENITES, be(r)'-me-nifes, a religious sect which flourished in Germany and other parts of Europe in the 17th century. They took their name from Jacob Behmen, Boehme, or Boehm, a celebrated German Hebmen, Bochme, or Bochm, a celebrated German mystic or theosophist, born near Göritz, in Upper Lusatia, 1575. His parents being poor, he received but little education, and learned the trade of a shoe-maker. Naturally of a serious turn of mind, he was given to studying the Holy Scriptures; and that passage seems deeply to have fixed itself upon his mind,—"My Father in heaven will give his spirit to them that ask him." He thou goar himself was aggressed. ask him." He then gave himself more carnestly to the study of divine things, and became the subject of divine revelations. On one of these occusions, in the 25th year of his age, he says that he was surrounded 25th year of his age, he says that he was surfounded by a divine light; and viewing the herbs and grass in the fields in his inward light, he sawinto their essences, uses, and properties. In like manner, he had revelations of God, nature, the creation, evil, &c., which e embodied in his rumerous writings. Its death took place in 1624. It was no part of Behmen's intention to found a sect. His object was merely to exhort Christians to true and pure life, and to instruct them in the mysteries of the true faith. He himself lived and died a genning Protestant a member of the Luand died a genuine Protestant, a member of the Lu-theran church. Formerly the doctrines of Behmen were viewed with great contempt by all but his own immediate followers; but latterly this unlettered rustic, this man of earnest principle and pious heart, has come to occupy a high place among the philosophers of his country. Hegel places him at the head of modern speculative philosophers, and Tieck and Novalis were enthusiastic admirers of his writings. Professor Maurice, in his article on Moral and Metaphysical Philosophy (Encyclopædia Metropolitana), says "that his obscurity was in a great degree the effect of unacquaintance with scientific language; but effect of unacquaintance with scientific language; but that through it all may be traced deep thoughts respecting God and man, by which philosophers might be greatly profited." After Behmen's death, his opinions spread over Germany, Holland, and England. His works were translated into English by the celebrated William Law, of Oxford. Henry More has written upon the views of Behmen, and it is said that many authorach, overath, from the works of Behmen and it is said that written upon the views of Behmen, and it is sight that many sattograph extracts from the works of Behmen were found among the papers of Bir Isaac Newton, During the Commonwealth, the doctrines of Behmen spread greatly in England, much to the annoyance of the Puritan clergy. Richard Baxter describes the Behmenites as men of greater meckness and more self-control than any of the other sectaries. Though

#### Being

Behmen has still many devoted admirers in the present day, especially in Germany, the Behmenites, as a re-ligious sect, may be said to be extinct. It is impossible, agrous sect, may be said to be extinct. It is impossible, within the limits of an article like the present, to give an intelligible account of the system of Jacob Behmen, and we must therefore refer the reader to Vaughan's Hours with the Mystics, or Francis Octley's Memoirs, 4c. of J. Behmen, Northampton, 1780.

Baine, bee's ing, is a term used in philosophy to destruction and the statement of the statement of

note whatever has a being or existence, either actually in the outer world, or ideally in the mind itself. Not only have the fictions of our mind a being, but even, according to some philosophers, nothing can be said to have a being.

BEIRAM. (See BAIRAM.) BRIT, bite, an Arabic word signifying a tent, hut, or other abode of men. It corresponds to the Hebrew beth, and forms a frequent compound in the names of places; as, Beit-at-Haram, the house of the sanctuary;

sacred house.

or 'sacred house.'

Bel and the Deagon, bel, is the name of an apocryphal and uncanonical book of Scripture. It was
always rejected by the Jewish church, and is extent
neither in the Hebrew nor Chaldee language, nor is
there any proof that it ever was so; hence St. Jerome
terms it "the fable of Bel and the Dragon."

BELAK, be-lat, in Mar., signifies to fasten a rope by winding it several times round a cleat, belaying-pin, or

BELLYING-Pins are wooden pins, made of ash and turned in a lathe, 16 inches long and 12 inch in dia-

meter at the upper end.

BELEMBITES, be-lem-nites (Gr. belemuos, a dart), in Geol., fossil remains of extinct naked cephalopods allied to the squid and the cuttle-fish. They are found in large numbers in the Chalk and Colite, generally as straight, solid, dart-like stones. These relies of crea-tures which thronged the seas of the secondary period have ever been objects of wonder, and the wildest speculations have been advanced to explain their origin. The popular names for them, such as devil's fingers, spectre-candles, arrow-heads, picks, and thunderholts, indicate the different views taken of their nature by the ignorant. To the philosoph-ers of the last

belemnite

a standing puz-

Was

the

RELEMNITES.

called were forth from time to time appear to us to be scarcely less absurd than the popular beliefs. It was said to be a product of electric action, and given the learned name of lapis fulniums, or thunderstone. According to other hypotheses it was a stalactic, a crystal, petrified amber, and lastly, when fossils began to be looked upon as actual organic remains, it was held to be the tooth, or perhaps the spine, of some unknown creature. It is now known to be the internal bone or shell of a cephalopod, and corresponds to the slender and insignificant pen of the common squid. Although the most common belemnites are mere tapering stones, some have been found so well preserved that naturalists have been able to form from them a vivid image of the living mollusk. "The belemnite," vivid image of the living mollusk. "The belemnite," writes the unknown author of "Vestiges of Creation," is an elongated conical shell terminating in a point, and having, at the larger end, a cavity for the residence of the animal, placed in the upper cavity, could raise or depress itself in the water at pleasure, by a pneumatic operation upon the air-tube pervading the shell. Its tentacula sent abroad over the summit of the shell searched the sea for prey. The creature had an ink-bag, with which it could muddle the water around it, The creature had an inkto protect itself from more powerful animals; and, strange to say, this has been found so well preserved, that an artist has used it in one instance as a nigment wherewith to delinente the belemnite itself." One genus of the Belemnite family, called *Belemnoteuthis*, and occurring in the Liss and Oolite, is occasionally discovered with the remains and impressions of the soft parts; namely, the mantle, body, and tentacles.

BELIEF, be-leef', is that state of mind in which one acquiesces in some truth, real or supposed. No doubt, every man in the world who believes in anything, even the most superstitious idea that ever found crodence, does so because he has some kind of a vague perception that the object of his belief is real and true. Bu the act of belief itself has puzzled the wise throughout all ages exactly to describe its character. One man alleges the act is intellectual, another says it is morel, a third affirms that it is emotional, and a fourth, who is likely as near the truth as may of the previous three, avers that it bears all those various characters at different times, and when applied to different sub-jects. Now it is intellectual, now it is moral, soon it is emotional; and it is as easy to describe it as it is to give a definition of instinct or of intuition. The reason of this apparent obscurity in the meaning of this word, is because men have no more general term that they are accustomed to apply to the same object. It is, accordingly, impossible to get behind belief, so as intelligibly to describe its character. It is emphatically "the light of all our seeing." There are, properly, four sources from which the sound beliefs of men are made up:—1st there is intuition or instinct; 2nd. there is our ordinary experience; 3rd. there are our scientific convictions, derived from the exercise of the two sources of knowledge, deduction and induction; 4th. there is testimony. These constitute the sources of our real convictions; but feeling and imagination have a great share in giving rise to illusory notions and superstitious beliefs in the minds of men. Man is responsible for every belief, real or illusory, which he maintains, provided, always, it was possible for him to discipline himself properly in the various kinds of knowledge in which he exercises his beliefs. This arises from the fact that we have all power over our minds in directing them to one object or another of study; and if this act, which is admitted on all hands to be volunif this act, which is admitted of an indust to be voluntary, be really so, for every voluntary act we commit, either directly or indirectly, we are entirely responsible. Belief is, no doubt, indirect in its connection with the conscience, but it is not, therefore, wholly irresponsible. Lord Brougham broached the irresponsible view of belief some years ago, in an inaugural address as lord rector of the Glasgow University; since which time it has been much discussed by inquirers into such matters.

BELINVERS, be-lee'-vers, an appellation first given to the disciples of Christ, but, towards the close of the let century, applied to those Christians that had been admitted into the Church by baptism, in contradistinction to catechumens who had not been baptized. and, consequently, were not entitled to church privi-leges. At present, the word is commonly used as sy-nonymous with Christians.

Bril, bel (Sax. bellan, to bawl or bellow), a metallic instrument which gives out a musical sound, caused directly by its own vibrations. The use of The use of bells in religious ceremonies is of great antiquity.

Amongst the Jews the high priest wore small gold bells

on the hem of his tunic. The pracbell at the raising of the host probably owes its origin to this circumstance. Large bells were first introduced into Christian churches at the town of Nols, in Campania, about 500; and diet. abbot A.D. Benedict, abbot of Wearmouth end Jarrow, first employed them

England in A.D. 680. Formerly all large bells were used only for religious purposes, and were manufactured by the monks. The process of casting was made a religious caremony; and, when complete, they were sprinkled with water and christened. A set of bells in perfect

## Bell. Diving

harmony is called "a maiden peal." Slight defects in the tone of a bell can be remedied afterwards. If the cound is too sharp, the bell is turned thinner; if too flat, the diameter of the bell is lessened by cutting the edge. The quality of a bell depends very much upon its shape. Bells with very fine tones have been made of glass; but the nature of the substance is too brittle to admit of constant blows from the clapper. Steel bells also give a good sound; but the vibrations only last for a short time. Ringing changes on peals of hells has always been a favourite emusement in England. It is reckoned that twelve bells would give 479,001,600 changes, which would take ninety-one years to ring at the rate of two strokes to a second. Dr. E. Beckett Denison, Q.C., in his discourse on bells, delivered at the British Institution, furnishes the following list of bells, with their respective weights:—Moscow, cast in 1736 (broken), 250 tons (?); another, 1817, 110 tons (?); three others, 16 to 31 tons; Norgorod, 31 tons; Almütz, 17 tons 18 cst. Vicena cast in 1711 17 tons 14 cst. AT tons, 18 cwt.; Vienna, cust in 1711, 17 tons, 14 cwt.; Westminster (Big Ben), cast in 1856, 15 tons, 83 cwt.; Westminster (Big Ben), cast in 1856, 15 tons, 83 cwt.; Effurt, cast 1497, 13 tons, 15 cwt.; Westminster (85: Stephen), cast 1858, 13 tons, 16 cwt.; Sens, 13 tons (P); Paris, cast 1680, 12 tons, 16 cwt.; Montreal, cast 1847, 12 tons, 15 cwt.; Congre, cast 1449, 11 tons, 3 cwt.; Breslau, cast 1507, 11 tons; Görlitz, 10 tons, 17 cwt.; York, cast 1845, 10 tons, 15 cwt.; Bruges, cast 1880, 10 tons, 5 cwt.; St. Peter's, Rome, 8 tons; Oxford, cast 1880, 7 tons, 12 cwt.; Lucerne, cast 1637, 7 tons, 11 cwt.; Antwerp, 7 tons, 2 cwt.; Brussels, 7 tons, 10 cwt.; Antwerp, 7 tons, 3 cwt.; Brussels, 7 tons, 14 cwt.; Ghent, 4 tons, 18 cwt.; Brussels, 7 tons, 14 cwt.; Ghent, 4 tons, 18 cwt.; Boulogne, new, 4 tons, 18 cwt.; Ghent, 4 tons, 18 cwt.; fourth quarter-bell, Westminster, cast 1857, 4 tons. 10 cwt. (?) Old Lineoln, cast 1610, 4 tons, 8 cwt.; fourth quarter-bell, Westminster, cast 1857, 4 tons. 10 cwt. (?) Old Lineoln, cast bell of Moscow, which is fractured after the manner shown in the annexed engraving, a great deal 17 tons, 18 cwt.; Vienna, cast in 1711, 17 tons, 14 cwt.; the great bell of Moscow, which is tractured after the manner shown in the annexed engraving, a great deal of gold and silver are said to have been thrown in as rotive offerings. The metal has been valued at £06,565. "Big Ben," the largest bell in England, was east in 1856 by Messrs. Warner, of Durham, under the superintendence of Dr. E. B. Denison and the Rev. W. Taylor, at an expense of £3,343, 148, 94. The composition was 22 parts conner and 7 tim. The The composition was 22 parts copper and 7 in. The diameter was 9 feet, 5½ inches; the height 7 feet, 10½ inches. The clapper weighed 12 cwt. This bell, having been found to be cracked, was broken up at the close of the year 1857, and in the following year Mesers. Mears, of Whitechapel, cast another bell with the same metal. This bell, which was named St. Stephen, is somewhat different in form from its predecessor, and is almost two tons lighter. Its diameter is 9 ft.
6 in.; height, 7 ft. 10 in. The clapper is only half the
weight of that of Big Ben, viz. 6 cwt. This bell was struck for the first time November 18, 1858. Like its struck for the first time November 18, 1858. Like its predecessor, it is cracked. The diameter of the bell of St. Paul's is 10 feet, the thickness 10 inches; the clapper weighs 180 lb. (See Acoustics, Bell-Maral.)

- Ref. Quarterly Review, Sept., 1854—Church Bells.

- Bell, Diving. (See Diving-Bells.)

- Belladdnna. (See Arroya.)

- Belladdnna. Lilt, bel-lin-dowl-nd, a very beautiful receips of Amorphia which wend. It is a nation of the

species of Amaryllis (which see). It is a native of the Cape of Good Hope, and was introduced into England in the early part of the last century. The flowering stem is about eighteen inches in height, and bears at its summit a cluster of drooping flowers of a delicate rose-colour.

Bull-Bied (Arapunga alba), a native of Guinea, and distinguished by a fleshy cylindrical appendage above the base of the bill. Generally, this appendage is decorated with a few fine feathers. Its voice is very peculiar, and much resembles the tolling of a bell. Waterton asserts that the sound it emits may be heard at a distance of three miles. It is of a pure white colour, and about a foot in length.

BELL, BOOK, AND CANDLE. (See EXCOMMUNICA

BELLE-DE-NUIT, bel'-de(r)-nue (Fr., beauty of night), the name given by the French to the Marvel of Peru (Mirabile Jalapa), on account of the flowers expanding at night. The name Belle-de-jour (beauty of day) is sometimes given to a species of Convolvulus, the 250

## Bell-Metal

flowers of which close at nightfull. (See MIRABILIS, CONVOLVULUS.)

BELLEBOPHON, beller-o-fon, in Geol., a gen. of fossil shells occurring in the Silurian, Devonian, and Carboniferons strats. As in the existing argument,

the shell consists of a single chamber.

BELLES-LETTERS (Fr.) is a vague, indefinite term, adopted from the French, and may be said to correpond to the Latin litera humaniores, or the English polite literature. It is difficult to say what branches of knowledge are comprised under this term, and what are not, for most of them have at one time been included in, at snother time excluded from it. Generally speaking, it comprises those branches of knowledge speaking, it comprises those branches of knowledge with which the imagination and tasts are chiefly con-cerned,—those that relate to beauty, harmony, gran-deur, and elegance, that tend to soothe the find, gratify the fancy; or move the affections. Poetry, rhetoric, history, and philology, are generally understood to come within the ephere of belles-lettres; logical and ethical studies belong to a higher sphere. "The exercise of taste and of sound criticism," says Blair, "is, in truth, one of the most improving employments of the understanding." "They are very intimately connected with the knowledge of ourselves. They necessarily lead us to reflect on the operations of the imagination and the movements of the heart, and increase our acquaintance with some of the most refined feelings which belong to our frame." They bring to light various quantance with some of the most remed seeing which belong to our frame." They bring to light various springs of action which, without their aid, might have passed unobserved, and which, though of delicate nature, frequently exert a powerful influence on several departments of human life." "Such studies have also this peculiar advantage, that they exercise our reason without fatiguing it. They lead to inquiries acute but not painful; profound, but not dry nor abstruse. They strew flowers in the path of science; and while they keep the mind bent in some degree, and active, they relieve it from that toilsome labour to which it must submit in the acquisition of necessary erudition, or the investigation of abstract truth."

BELL-PLOWER. (See CAMPANULA.)

Bell-Gable, or Bell-Turnet, or Bell-Cot, in Arch.—In some small churches and chapcis, where there are no towers, there is frequently a bell-gable or turret at the west end of the structure, in which the bells-sometimes only one, sometimes two or three-are hung. A few of these erections are of Norman are hung. A few of these erections are of Norman date, but the larger number are later, and many of them are Early English. They are extremely picturesque, and are well placed on small churches and chapels where the funds are insufficient to provide towers. Besides the bell-gable, a smaller erection of a similar kind is often provided for the sanctus bell, on the apex of the eastern end of the roof of the nave.

BELLIGERUNT, bel-lij'-e-rent (Lat. bellum, war, and gerere, to carry on), is a term applied to nations waging or carrying on war against each other.

Bellis, hel-lis, in Bot., the Daisy, a gen. of plants belonging to the nat. ord. Compositae, sub-ord. Corymiterae. The receptacle is without scales, and upon it are arranged two kinds of flowers,—ligulate, or strap-shaped, and tubular. The ligulate flowers, which are white in the common daisy, form the ray, or outer circle. They have no stameus, but each has a single pistil, which, at the top, divides into two branches, forming stigmas. The yellow tubular flowers clustered together within the ray are hermaphrodite; that is to say, they have both stamens and pistils. The involucre is composed of two rows of bracts. The fruit found at the base of every little flower, whether ligulate or tubular, is without a pappus, and contains a single seed. The best-known species is B. perennie, the common daisy. The roots of this are perennial; the leaves are obovate, spathulate, single-ribbed, crenate, and dentate. (See LRAF.) It blessoms nearly all the year round, and is constantly found with opened flowers from March to October. In a charming essay upon this wild plant, Mrs. Lankester writes:—"Throughout Great Britain, we find its tiny bright flowers apringing up on every lawn and grassy plot, by waysides, on mountain-slopes, and is almost every country in

Europe.

Bell-Metal.—Science and experience together have shown that an alloy of 80 parts of copper and 20 parts

#### Bellows

of tin makes the best bell-metal. Bells, however, are made of brass, antimony alloyed with tin, German silver, silver, and gold. The hand-bells found by Mr. Layard at the palace of Nimroud were composed of 1 part of tin and 10 parts of copper. Probably these bells, being of Phosnician manufacture, contained tin which had been obtained in Britain 3,000 years ago. Indian gongs contain 80 parts of copper and 20 of tin. In ordinary bells, lead and zinc are often substituted for tin. When silver is mixed with bell-metal, it injures the tone of the bell.

Bells, however, are made and since are often substituted for tin. When silver is mixed with bell-metal, it injures the tone of the bell.

Bells, however, are

ling air forcibly through a tube. The most ordinary kinds consist of two boards, of a circular or oval form each provided with a projecting handle, and two or three hoops are bent between the hoards. To the edges a noops are bent between the locats. To the edges a piece of leather is nailed, broad in the middle, in order to cover the hoops, and thus form a small chamber, which can be dilated or contracted by moving the handles. A pipe is fastened to the lower board, passing into the chamber, and there is also a round hole in this board, which is covered with a leathern valve opening in-wards. By dilation and contraction, air is inhaled by the valve-hole, and then forced through the nozzle of the pipe in any direction that may be desired. It is used in private dwellings for the purpose of blowing a fire into greater activity: it is also used for forges and furnaces. Strabo attributes the discovery of the bellows to Anacharsis the Scythian. The principle of the hydrostatic bellows, an instrument made for the purpose of showing that the pressure of fluids is as their perpendicular heights, has been applied in the construction of the hydrostatic press. Many operations in manufacturing art require a very high temperature. Formerly this was entirely effected by the bellows; the hot-blast is, however, now generally employed. (See BLOWFIPE, METALLURGY.)
BELLS, in Mar.—On board ship the time is divided

into periods of four hours each, and as each hulf-hour passes it is marked by striking on a bell. This bell is usually hung to the beam of the forecastle, but sometimes it is attached to a beam near the mizen-mast. One stroke on the bell denotes that half an hour has passed, two strokes that an hour has passed, and so on, adding a stroke for each half-hour. Thus, "five bells" adding a stroke for each half-hour. Thus, "tire bells" would signify that two hours and a half had passed, and "eight hells" signifies that the four hours, or complete "watch," is over. The bell on which the time is struck is sometimes used during foggy weather to show that the ship is on a starboard tack; when she is on a port-

tack, a drum is beaten.

BELLY. (See ADDOMEN.) BELOMANCY, be'-lo-man'-se (Gr. belos, an arrow, and manteia, prophecy), denotes a species of divination by means of arrows, common among the Arabs and other eastern nations. It is practised in various ways; but the most common is to shoot off a number of arrows with inscriptions attached to them, and to be guided by the inscription upon the arrow which is first

found.

BELOPTERA, be-lop'-te-ri (Gr. belos, dart, pteron, wing), in Geol., a fossil resembling a belemuite, but less pointed, and having a wing-like projection or process on each side. It occurs in Tertiary strata, and was evidently the internal bone of a cephalopod. The name Belosepia (Gr. sepia, cuttle-fish) is given to another kind of belemuite found in Tertiary deposits; and that of Beloteuthis (Gr. teuthis, squid) to one shaped like a spear-head occurring in the Lins.

BELT, belt (Lat. bullens, a baldrick or girdle), in Astron, a term applied to some dark stripes or zones that appear on the surface of the planet Jupiter paral-

that appear on the surface of the planet Jupiter paralled to its equator. (See JUFITER.) Orion's Belt is tigured by three stars in a direct line with each other, situated horizontally in the centre of the constellation.

Situated horizontally in the centre of the constellation.

BRUTEIN, BELTANH, or BEALTINE, bel'tain, the
name of a great heathen festival, once common to all
the Celtic nations, and traces of which still exist in
some parts of Scotland and Ireland. The name is derived from tine, tire, and Beal, or Bel, the sun, or god
of light; and in the Irish language the month of May
is still called Bealtine. The festival was held on the
lat of May: large fires were kindled on the summits
of the highest hills, and estite were driven through
them. It is said to protect them from contagious disthem. It is said to protect them from contagious dis-

### Beucher

All the inhabitants of the district quenched their fires on that day, and rekindled them from these fires. A similar festival seems also to have been held on the 1st

similar restival seems also to have been held on law law of November. (See MAYDAY.)

BELUGA, be-lu'-gd, a gen. of Cetacsa belonging to the Delphinida, or Dolphins. It has a broad blunt head, and no produced snout; thus differing from the rest of the family to which it belongs. Its form is principally characterized by the softness of its curves, and the clear white colour of its skin, which is so tender the clear watte colour of its skin, which is so tender-that it often fails to retain the harpoon. The belugs also differs from the ordinary family of dolphins in having fewer teeth, which fall out before the animal is old, and it has no dorsal fin. It usually attains the length of thirteen feet, and feeds principally on fish.

BELVIDERS. (See KOCHIA.)
BELVIDERS, or BELVEDERS, bel-ve-deer' (Ital-bella, fair, beautiful; Lat. videre, to see), a name given, in Arch., to a place erected on the top of any building, from which a good prospect of the country around can be obtained. The structure is of Italian origin, and is commonly found in houses at Rome. The Belvidere at the Vatican is one of the most remarkable in existence, being built in the form of a horseshoe, having a gallery inclosed at the back running round the semicircular part, and a balustrade in front. It commands a magnificent view of the country about Rome, extending as far as the Apennines. In France and England the term is applied to summer-houses or buildings erected in gardens and parks, from some of which a good view of the surrounding scenery can be obtained.

Belvisiace. bel'-vis-i-ai'-se-e (from the gen. Bel-

visia, named after its discoverer, P. de Beauvois), a small nat. ord. of dicotyledonous plants, in sub-class small nat. ord. of dicotyledonous plants, in sub-class Calyciflorer, comprehending only two genera, namely, Asterauthos and Aupoleona, or Helvisia. These include four species, which are large shrubs, with smooth leathery leaves, all growing in tropical Africa. The flowers grow in threes, sessile in the axis of the leaves, and are extremely curious. The calyx is a thick leathery cup, divided into five segments. The corolia consists of three divinet whenly of midd notals the consists of three distinct whorls of united petals; the onter one turning back over the calyx; the second one is a narrow membrane divided into numerous segments; and the third forms an erect cup, and contains the stamens, which are united, so as to make a sort of inner cup. The fruit is a soft berry, with large kidney-shaped seeds. The pulp of the fruit is edible, and the pericarp contains much tannin.

BENERIDGE BEDS, bem'-bridj, in Gool., the name given to an important group of upper cocene strata, resting on the Osborne or St. Helen's series, and capped by the Hempstead beds. In the Isle of Wight this group is principally developed. Beginning at the bottom, we find the Bembridge limestone. This bed consists of a pale yellow or cream-coloured limestone, interstratified with clay or crumbling marl, and is from 20 to 25 feet thick. Upon this we find the oyster-hed, a few feet of greenish sands, containing oysters (Ostræa vectensis) in great abundance, capped by a band of hard septerian stone. Resting on this are unfossiliferous mottled clays, alternating with fossiliferous laminated clays and marls. The latter contain the characteristic shell Cyrena pulchra. Lastly we come to maris and laminated grey clays containing

BEN, OIL OF, an oil obtained from the fruit of the Moringa ptergosperma. It is a thick yellowish fluid, possessing the property of seldom turning rancid, which renders it of great use in perfumery.

BENCHERS, benehi-are, in the inns of court, are the senior members of the society of each house or inn, to whom the government of its affairs is committed; and out of the number one is annually chosen as treasurer. out of the number one is annually chosen as treasurer. orders; but doubtless they were originally sacrificed. The sole power of calling students to the bar, by which

they become barristers, and of disbarring them, and thereby depriving them of their qualification, for misthereby depriving them of their qualification, for misconduct, is vested in them, subject to an appeal to the
judges as risitors of the inn. These inns are four in
number; viz., the Inner Temple, the Middle Temple,
Lincoln's Inn, and Gray's Inn.
BEND, bend (Sux. bendan), in Her., one of the nine
principal ordinaries, occupying a fifth part of the field
when uncharged, but a third part when it has any
device or charge upon it. It is formed by parallel
diagonal lines drawn from lett to right or from the

diagonal lines, drawn from left to right, or from the

BEND.

dexter chief to the sinister base. When the term bend is mentioned without any addition, the bend dexter is always meant. The bend has four diminutives,—the bendlet, balf the width of the bend; the garter; the ribbon; and the cost, or cotice, a narrow stripe generally borne on either side of the bend.

Charges are said to be in bend, or per bend, when they are placed in the direction of the bend from the dexter chief to the sinister base.

BENDING, bend'-ing, in Mar., the tying of two ropes or cables together: thus, to bend the sail is to make it fast to the yard; to bend the cable, to make it fast to the ring of the anchor.

BEND SINISTER (Lat. sinister, the left), one of the nine principal ordinaries, being exactly the reverse of the bend, similarly formed, but by lines drawn from the sinister chief to the dexter base, or from right to left. It has two diminutives; the scarp, half the width of the bend, and the baton, used as an abatement to denote the illegitimacy of the bearer of the coat.

BRNEDICITE, ben'e-dis'-i-te (Lat.), is the name given to the hymn or song of the Three Children in the licry furnace, from the Latin version of it, beginning, Benedicite omnia opera Dominum. The singing of the Benedicite in the Christian churches is very ancient, for it appears to have been in universal use as early as ior is uppears to have been in universal use as early as the time of Chrysostom. In the English church, the Benedicite was, by Edward VI.'s First Book, prescribed to be used during Lent; but, by the present Prayerbook, it may be said or sung at the morning service, instead of the Te Deam, whenever the minister thinks fit.

BENEDICTINE FATHERS, is the name given to cele-brated editions of the works of the Fathers, from their having been edited by some of the most celebrated of

the Benedictine monks in France.

Benedictines, ben'-e-dik'-tins, an order of monks taking their name from their founder, St. Benedict, who flourished in Italy in the early part of the 6th century. They spread very rapidly, and for the next three centuries, almost all the monks in the West might be said to be Benedictines. At first they had no dis-fractive dress, but afterwards they were black; whence they came to be called also Black friars. The decline of monastic discipline led to the reforms of Benedict of Monastic discipline lea to the reforms in Enclose of Aniana in the 8th century, and of the abbot of Clugny in the beginning of the 10th. The Cluniaes, in place of the discordant and uncertain rules that had hitherto existed, made fixed regulations concerning the hours of worship, the obedience, discipline, and government of their monasteries, which were soon imitated throughout Europe. The rules of St. Benedict, as observed by the English monks previous to the Reformation, were as follows: they were obliged to perform their devogo two and two together; every day during Leut they were obliged to fast until six in the evening, and to diminish their usual time of sleeping and eating; but they were not allowed to practise any voluntary aus-terity without the consent of their superior; they never conversed in their refectory at meals, but were obliged to attend to the reading of the Scriptures; for small faults they were shut out from meals; for greater, they were debarred religious commerce and excluded from were debarred religious commerce and excluded from the chapel; while incorrigible offenders were expelled 10,421. the 15th century, this order had 15,107 monasteries, of which, after the Reformation, only about 5,000 were left, and at present there are only about 800. This order has produced a great number of learned men, and it did much in the way of fostering and spreading Christianity, civilization, and learning in the Middle

Ages.

BENEDICTION, ben'-e-dik'-shon (Lat. benedico, I speak well), is the invoking of the divine blessing upon individuals; sometimes, also, upon animals and things. The ceremony of blessing is of very remote antiquity, for we read of the Jewish patriarchs, before they died, invoking the blessing of God upon their children. At a later period, the priests were commanded to bless the people; and Christ himself sanctioned the custom, in that, before parting from his disciples after his resurrection, "he lifted up his hands and blessed them." In the ritual of the Roman Catholic church the benediction, in different forms and words, occupies the benediction, in different forms and words, occupies an important place; and it constitutes an essential part of many of its ceremonics. One of the most imposing of these is when the pope, on Easter Sunday, after mass, in full pontificals, and attended by the cardinals end prelates, pronounces his benediction with et orbi (on the city and the world), from the great gallery in front of St. Peter's church, before many thousands of kneeling spectators. In the liturgy of the Church of England there are but two benedictions, and in the Church of Steptand only one, reconsured at and in the Church of Scotland only one, pronounced at the end of the service.

BENEDICTUS, ben'-e-dik'-tus (Lat., blessed), the name of one of the hymns ordered to be said or sung after the second lesson in the morning service of the Church of England. It is so called from its begin-ning with that word in the Latin version.

HENEFICE, ben'e-fis (Lat. beneficium, a good deed, a favour), in authors of the Middle Age, in used for a fee, sometimes more peculiarly danominated beneficium militare. In this sense, benefico was an estate in land, at first granted for life only; so called because held ex mero beneficio of the donor; and the tenants were bound to swear fealty to the lord, and to serve him in his wars. In after-times, as these tenures became perpetual and hereditary, they left their name of benefice to the livings of the clergy, and retained to themselves the name of feuds. Benefice, in an occlesiastical sense, is a church endowed with a revenue for the performance of divine service, or the revenue itself assigned to an ecclesizatical person, by way of stipend for the service he is to do to that church. All church preferments except hishoprics are called benefices, and all benefices are, by the canonists, sometimes styled dignities; but we now ordinavily distinguish between benefice and dignity, applying dignity to bishopries, deaneries, archdeaconries, and dignity to bishopries, deaneries, archdeaconires, and probendaries, and benefice to patronages, vicarrages, and donatives. Benefices are divided by the canonists into simple and sacerdotal. In the first, there is no obligation but to read prayers, sing, &c. Such are canonicies, chaplainships, chantries, &c. The second are charged with the cure of souls, or the direction and guidance of consciences; such as vicarages, rectories, &c. The Romanista again distinguish benefices into regular and secular. Until the 4th century, the revenues of the Church consisted principally in the revenues of the Church consisted principally in alms and voluntary contributions, and were distributed under the directions of the bishop; but when the Church came to possess lands, part thereof were assigned for the subsistence of the clerks, and called benefices, of which we find some traces in the 5th and 6th centuries. But it does not appear that the allot-ments were positively defined till about the 12th. At first each was contented with a single benefice; but pluralities were by degrees introduced, on a plea that in some places a single benefice was not thought a in some places a single penetice was not connected. By a return to parliament in 1817, the number of benefices in England were stated to be 10,421. (Sce Living, Tirries, Parson.)

Benefice in Commendam is that, the direction

my interest in any funds or estate held in trust by

BERFIT OF CLERGY, ben'e-ft, originally denoted the privilege or exemption which was possessed by the clergy from secular jurisdiction. In early times, clergy-men were in certain cases exempt from punishment men were in certain cases exempt from punishment by secular judges, and could claim their privilegium clericals. This privilege, however, did not extend to high treason. Afterwards, reading, as being at that time almost solely confined to the olergy, came to be the test of one's being entitled to the benefit of clergy. On a condemned man demanding "to be admitted to his book, the judge commonly giveth him a Psatter, and turneth to what place he will. The prisoner readeth so well as he can (God knoweth sometimes very slendegly); then he (the judge) asketh of the bishop's commissary, 'Legit at clericual' (Does he read like a clergyman?). The commissary must say 'Legit' or 'Nou legit'; for these be words formal, and our men of law be very precise in their words formal. \* Legit' or 'Nou legit;' for these be words formal, and our men of law be very precise in their words formal. If he say legit, the judge proceedeth no farther to sentence of death; if he say non, the judge forthwith proceeded to sentence.' In 1888, when reading had become a less rare accomplishment, a distinction was made between the clergy and those who were morely able to read; so that one of the latter class, after having once been admitted to the benefit of clergy, we are not allowed to claim the privilege a second time. was not allowed to claim the privilege a second time unless be produced his orders; and those who had ence claimed the privilege were burned on the hand, in order to mark them. The formality of reading was done away with by 5 Anne, c. 6, which enacted that the bencht of clergy should be extended to all who are curled to it, without requiring them to read. do it, without requiring them to bergy had previously been adopted as a bergy had previously been adopted for form canital punishment for Benefit ress freedon from capital punishment for it was not till 7 & 8 Geo. IV. c. 28, that the coegy was cutirely abolished.—Ref. English term f. n ir - Arts and Sciences.

TENEFIT SOCIETIES. (See FRIENDLY SOCIETIES.)

IFMEVOLENCE, be-nec'o-lens (Lat. benecolentia, from bene, well, and colens, wishing), in Ethics, denotes an entrest desire for the good of mankind, manifesting itself, as ability and opportunity may offer, in acts of kindness and charity towards all. Some philosophers attribute this affection to self-love; others to an instinct inherent in our nature. "It is the benevolent passions only," says Adam Smith, " which can exert themselves without any regard or attention to propriety, and yet retain something about them that is engaging.

BENEVOLENCE, in Eng. Hist., was a means of raising money formerly resorted to by the kings of England, in violation of the Magna Charta. As the name implies, in violation of the Magna Charta. As the name implies, it was nominally a gratuity; but in reality it was a forced loan, exacted with or without the condition of repayment. Edward IV, had frequent recourse to this means of raising money; but by a statute of his successor, Richard III., it was declared to be illegal. Benovolences were, however, exacted by Henry VII., and occasionally, by means of circulars nuder the private live his successors. 13 (Barlas II. stat 1 a.4 seal, by his successors. 13 Charles II, stat. 1, c. 4, provides that no voluntary aid can be raised on behalf of the sovereign but by the authority of parliament; and the Bill of Rights, in Feb. 1689, declares that the levying of money for or to the use of the crown, by pretence of prerogative, without grant of parliament, is illegal.

BENGAL LIGHT, or BENGAL FIRE, ben-gawl', a mixture composed of one part of tersulphide of antimixture composed of one part of tersulpinde of anti-mony, two parts of sulphur, and six of nitrate of potash. The materials are reduced to a fine powder, and tho-roughly mixed. When ignited, the mixture burns, giving out a remarkably brilliant and searching light, It is used in cases of shipwreck, and is capable of illu-minating the sir for a considerable space around. As the consequently, the Bengal light cannot be used with safety in inclosed or covered places; it is, however, much used in pyrotechny.

BENGALER LANGUAGE. (See HINDOSTAN, LANGUAGE.)

GUAGES OF.)

BENISH DAYS, be'-nish, among the Egyptians, is a term applied to three days of the week (Monday, Wednesday, and Saturday), from their being days of less ceremony in religion than the other four. They slowly changed into a crystalline mass.

#### Benzoine

are named from the benish, a garment of common use, not of ceremonious.

BENISON. (See BENEDICTION.)
BENISON. (See BENEDIX.)
BENISON. (See BENEDIX.)
BUNT GRASS, the common name for the gen. Agreetis

(which see).

BENZILE, ben'-sil, in Chem., an oily solid, crystal-lizing in hexagonal prisms, formed from benzoine by the setion of chlorine.

BENZINE, ben'-zine, another name for benzole. (See BENZOLE.)

RENZOENE, ben'-zo-ene, another name for toluyl, which see). This word has been abandoned by Engwhich see). lish chemists on account of its being easily confounded with benzoine.

BENDUE ACID, ben-zo'-ik (C<sub>14</sub>H<sub>2</sub>O<sub>3</sub>HO).—An acid obtained from gum-henzoin. It is also found in the balsams of Tolu and Peru, in storax, and in the urine of herbivorous animals. It is easily prepared by sublimation. The powdered gum-henzoin is placed in a shallow iron pan which is covered with the country of the powdered gum-henzoin is placed in a shallow iron pan which is covered with the country of the powdered gum-henzoin. with a cone of bibulous paper. A heat of 300° Fahr, is applied to the pan, and the whole apparatus is covered by a second cone much larger than the first, made of non-absorbent paper. The vapours of benzoic acid rise through the bibulous cone, and condense on the inside of the larger one; being thus prevented from fulling back into the heated gum-benzie. zoin. Benzoic acid forms white glistening needles, having an agreeable aromatic odour, and a hot, bitter taste. It melts at 24% sublimes at 293%, and boils at 462°. Its vapour may be kindled, burning with a smoky flame. It dissolves in 200 parts of cold water and 25 of hot. It is readily soluble in ether and alcohol. It combines with the alkalies, earths, and metallic not. It combines with the alkalies, earths, and metallic oxides, forming benzoates. It forms sulpho, nitro, and chloro-benzoic, by the substitution of atoms of sulphuric acid, perexide of nitrogen, and chlorine, for atoms of hydrogen. Its other compounds are too numerous and unimportant for mention here.

BENZOIC ALCOHOL, the sleohol of the benzoic series,

the hydrated oxide of toluyl, i.e.

 $C_{14}H_1 + O + HO = C_{14}H_6O_2$ Toluyl, or benzoene. Benzoic alcohol. It bears the same relation to benzoic acid that vinous

alcohol does to acetic acid. Oxidizing agents convert heavier than water, and boiling at 400°.

Bunzoic Ether.—Oxide of benzoene, or toluyl. It

is procured by heating benzoic alcohol and anhydrous boracic acid together in a closed vessel for some hours.

BENZOIC GROUP.—One of the groups of the benzoic ries (which see). The members of the benzoic group series (which see). The members of the benzoic group are analogous to those of the vinic or ethylic group, being all derived from a primary radical Lenzoil, us those of the latter group are from othyl (which see). They are nearly all obtained from oil of bitter almonds.

BENZOIC SERIES .- Avery perfect and numerous series of organic compounds, containing eight groups :

1. Phenylic group. 2. Quinonie ,,

5. Anisie group.
6. Cinnamic ,,
7. Naphthalic ,,

4. Salicylic , 8. Indigotic ,, The benzoic series has lately been rendered very im-

portant from containing beuzole and aniline, the sources of the coal-tar dyes.

BENZOIN, OF GUM-BENJAMIN, ben-zo'-in, or ben'-coin, a fragrant balsam obtained from the Benjamin-tree. (See STYRAX.) It exudes from incisions in the bark, and soon hardens by exposure to the air. Two kinds are distinguished in commerce by the names of Siam and Sumatra benzoin. The former is most esteemed in England. Benzoin is used in medicine as a stimulant expectorant. It is, however, principally employed for the preparation of benzoic acid, and as an ingredient in the incense used in Greek and Roman Catholic churches. It is also an

in Greek and Roman Cutholic churches. It is also an ingredient in funigating pastiles and court plaster. The agreeable edour produced by burning benzoin is due to the evolution of the vapour of benzoic acid.

Benzoine, benzoi-ine.—This compound must not be confounded with benzoin and benzone (both of which see). It is isomeric with essence of bitter almonds, hydride of benzoyl, from which it is produced by the action of an alcoholic solution of potash, the oil being slowly changed into a crystalline mass.

BENEOLE, ben'-role (C<sub>1.0</sub>H<sub>a</sub>).—A hydrocarbon of considerable importance, derived from coal tar. It was first obtained by Faraday from a liquid produced by compressing oil gas, and was called by him bicarburetted hydrogen. Mitscherlich afterwards obtained it from benzoic acid; and latterly Mansfield has procured it in large quantities from coal-naphtha and gas-liquor. It in large quantities from coal-naphtha and gus-inquor. As a simple, volatile, colourless, and mobile liquid, with a peculiar odour, having a specific gravity of 0.85, and boiling at 177°. Exposed to a temperature of 32°, it condenses into crystalline masses, which melt at 40°. It is insoluble in water, but dissolves freely in alcohol, ether, and oil of turpentine. It is greatly used in the arts, being an excellent solvent for india-rubber, guttapercha, wax, camphor, and fats. The property of dissolving fats and oils, added to its great volatility, randers it very useful for removing grease-stains from articles of dress. It is sold for this purpose under the name of "benzine collas," at about three or four times its real value. It has lately received a most important application as the source of aniline (which see). It forms substitution compounds with bromine, chlorine, and iodine, by the replacement of one, two, or three atoms of hydrogen by one, two, or three atoms of these bodies, giving rise to mone, bi., and tri-chlorbenzole, &c. It also forms similar compounds with peroxide of hydrogen, the most important of which for these barries and the final control of the cont with peroxide of hydrogen, the most important of which is nitro-benzole, or artificial oil of bitter almonds. It is made by adding benzole very gradually to funning nitric acid. On cooling, the nitro-benzole separates as an oil, and is purified by washing and redistillation. It is a yellowish oil, which solidifies in needles at 37°, and boils at 415°. It has a sweet taste, and its odour closely resembles that of bitter almonds. It is much used in perfumery under the name of "essence of mirbane." Its principal use is in the manufacture of mirbane for dwales a purposes hyposesia such batter? of milius for dyeing purposes, by passing sulphureture of anilius for dyeing purposes, by passing sulphureture hydrogen through it, or by acting on it with protacetate of iron. Benzole is also known as bearing and

BENZOYL, hen'-zoil (C1, H2O2), the oxygen radicle of the benzoic group, from which all its members are derived, as all the members of the vinous group are derived from othyl. The following examples will show this analogy :

 $\begin{array}{lll} \log y & & & \log y & & \\ \mathbf{C_1} + \mathbf{H_3} \mathbf{O_2} + \mathbf{HO} + \mathbf{O} & = \mathbf{Acetic\ acid.} \\ \mathbf{C_1} + \mathbf{H_3} \mathbf{O_2} + \mathbf{HO} + \mathbf{O} & = \mathbf{Benzoic\ acid.} \\ \mathbf{C_4} & \mathbf{H_3} \mathbf{O_2} + \mathbf{H_3} & & = \mathbf{Alcohol.} \\ \mathbf{C_3} & \mathbf{H_4} \mathbf{O_3} + \mathbf{H_3} & & = \mathbf{Benzoic\ alcohol.} \\ \end{array}$ = Benzoic alcohol

BRNZOYL, HYDRIDE OF (C1.4H.O2H), essence or oil of bitter almonds.—The hitter-almond cake, left after he extraction of the tixed oil, is mixed with water and fermented, until the whole of the amygdain is decomposed. The mass is then distilled, and the distillate is purified by agitating it with milk of lime and chloride of iron. The hydro-cyanic acid contained in it is thus transformed into Prussian blue. Pure hydride of benzoyl is not poisonous. It is a limpid, highly-refractive, inflammable liquid, which boils at 356°, and dissolver in 30 north of water. dissolves in 30 parts of water. Alcohol and ether dis-solve it in all proportions. Exposed to the air, it gradually absorbs oxygen, and becomes converted into benzoic acid. It is the aldehyde of benzoic alnohol :--

 $C_{14}H_{8}O_{9} - H_{9} = C_{14}H_{8}O_{9}$ Benzoic alcohol. Hydride of benzoyl.

Braderidacem, ber'-ber-i-dai'-se-e, in Bot., the Bar-berry fam., a nat. ord. of dicotyledonous plants, in the sub-class Thalamilora, consisting of shrubs and herbaccous perennials. The leaves are alternate and compound; frequently they appear to be simple; but, in such cases, it will be found that the blade is articulated to the petiole, which is evidence of their compound mature. The atem is often spiny, but generally free from hairs. The spines are nothing more than the bardened weins of some of the leaves between which the parenchyma is not developed. The flowers are sometimes solitary, sometimes in racemes or panicles. The calve consists of three, four, or six deciduous sepals; the petals are hypogynous, and either equal sepais; the petais are hypogynous, and either equal any decided progress in civilization. They are conto this sepais in number, and opposite to them, or twice stantly fighting, either samongst themselves or with the small stantly fighting. Their dwellings are mostly clay number, and opposite to them; the anthers are two-called, each cell opening by a curious recurved valve their villages. The mines of lead and iron ore in the 254

from the bottom to the top; the carpel is solitary, and has but one cell; the fruit is either a berry or a capsule. The order includes twelve geners, which together contain 100 species, natives of the temperate parts of Europe, Asia, and America, some being exceedingly common in the mountainous regions of the north of India. The plants have acid, astringent, and bitter properties; their acidity is due to the presence of oxalic acid.

Oranic acid.

Bribbing, ber'-be-ris, in Bot., the typical gen. of the nat. ord. Berberidacea, consisting of numerous species, found in temperate climates in most parts, except Australia. These are shrubs, often spiny, with yellow flowers and acid berries. The three whorls of organs in the flower are each made up of six parts: organs in the nower are each made up of six parts: thus, there are six sepals in the calvx, six petals in the corolla, and six stamens. The latter are remarkable for their irritability; for if touched at the base by an insect, or even with the point of a pin, they start up from their natural reclining position, and close upon the pistil. The most interesting species is B. wilgaris, the common barberry, which is usually a bush from four to six feet high, but which, in Italy, sometimes becomes as large as a plum-tree. It is a very ornamental plant, especially when covered with fruit. The berries are of an oval shape, and, when ripe, generally of a bright-red colour, but sometimes whitish, yellow, or almost black. They are very acid, and not fit to be eaten raw; but when boiled with

sugar, they form a most refreshing preserve. They are sometimes pickled, to be used for garnishing dishes, and occasionally they are put into sugarplums or comnts. The bark and stem are very astringent, and yield a bright yellow dye. A fungus, which has been named Æcidium berberidis, is frequently found on the underside of the leaves; und the common, but erroncous opinion,

that the minute spores of this parasite will produce rust in corn, has prevented the general employment of the barberry as a hedge-plant, for which it is admirably adapted. Of the numerous product of Parkers which is the same and the same rous species of Berberi: which are cultivated in Britain as ornamental shrubs, the finest is undoubtedly B. aristata, the bristle-leaved barberry. This is a hardy evergreen, predacing excellent fruit. It is a native of Nepaul, and was introduced into this country about

forty years ago.

BEREERS, ber-bers (Lat. barbari).—The inhabitants of the northern part of the Great Desert and the mountainous districts of Barbary. The whole of these scattered tribes are the descendants of the aboriginal inhabitants of Northern Africa. Their number is calcu-lated to be at the present time between three and four millions. They are of the middle stature; their commillions. They are of the middle stature; more com-plexion varies from red to yellowish-brown; and they are strongly and compactly made. The head is much more European than African in type. Their eyes and hair are dark, and they are cruel, suspicious, and im-placable in their disposition. In nocient times the Borbers formed the largest part of the population dwelling on the northern coast of Africa; but upon the great Arabian invairation, in the 11th centure, they awaining on the northern coast of Africa; but upon the great Arabina immigration, in the 11th century, they were driven back to the mountains and desert regions, where they now live. In Algeria they are called Kabyles, and are as yet unconquered by the French. In Morocco they are called Shelloch; and in Tripoli they only pay a nominal allegance to the Turks. The Berbers who inhabit the desert have become much upixed with the very range and are called Turks or mixed with the negro race, and are called Tuarie, or Tawarek, by the Arabs. The whole race, at the present day, seem to possess a wild spirit of independence. which prevents them from uniting together or making any decided progress in civilization. They are con-

#### Berchta

Bernicle Geese

Atlas Mountains are worked by them. They have water-mills and oil-presses, and many of them have large herds and flooks of cattle and sheep. They are also agricultural, and have an especial liking for the rearing of fruit-trees. The Berbers were formerly Christians; but since the Arab invasion they have all become Melaymetra.

become Mahometans.

BERGHTA, bairg'-ta (Old Ger. perdata, lightning, shining; whence the name Bertha), in German Myth., is a spiritual being, probably the same, under a differ-ent name, as the Hulda of North Germany; but in North Germany, Halda is regarded as a benign spirit; whereas, in South Germany, Berchta is looked upon as a malevolent being, and her name is made use of to frighten disobedient children. Berchta is especially charged with the overlooking of spinners.—Ref. Brock-Convertations Lexikon.

HEBBANS, be-re'-dne, in Ancient Church Hist., were the inhabitants of Berea. They are highly commended in Scripture for their ready reception of the

Gospel, upon a fair and impartial examination of its agreement with Old Testament prophecies.

Bergans, in Modern Church Hist., a sect of dissenters from the Church of Scotland, who take their name from, and profess to follow, the example of the ancient Bereaus, in building their system of faith and practice upon the Scriptures alone, without any regard to human authority. Their founder was Mr. John Barclay, who, in 1773, left the Church of Scotland because he had not been presented to the parish church of Fettercairn, though the people were unanimous in his favour. The Bereans agree with the great body of Christians respecting the doctrine of the Trinity, and with the Calvinists regarding predestination and election. They differ from other sects in rejecting all natural religion; in holding faith to be a simple cre-dence of God's word, and always accompanied with a personal assurance of salvation; in considering un-belief as the sin against the Holy Ghost; and in interpreting almost all the Psalms as typical or prophetical of Jesus Christ, and reckon it a perversion to apply any psalm to individual spiritual experience. The Bereaus were at one time pretty numerous in Scot-land, but they are now nearly extinct.

BERENGARIANS, ber-en-gair'-i-ons, in Eccl. Hist., a denomination that arose in the 11th century, and adhered to the opinions of Berengarius, archdeacon of Angers, who apposed the Roman Catholic doctrine of Angers, who exposed the Monka Catholic detrills of transubstantiation, and usserted that the bread and wine in the Lord's Supper were not really and essen-tially, but only figuratively, changed into the body and blood of Christ. The Roman Catholics ranked the Berengarians among the most dangerous of heretics.

BERGAMOT, OIL OF ESSENCE OF, ber'-ga-mot, a fragrant essential oil, obtained by expression or distil-lation from the rind of the Bergamot orange. (See CITRUS.) It is extensively employed in perfumery for scenting pomades, and as an ingredient in most compound essences; such as eau de Cologne, eau de mille-

fleurs, and Jockey-club bouquet.

BERG-MAHL, bairy'-mal (Sweddish, mountain-meal).—
The name given to a whitish earth, consisting almost entirely of the flinty shields of microscopic plant-growths. (See DistrIGMACE.E.) It occurs in bog and aucient lake deposits in many parts of Northern Europe, and, during times of great scarcity, it has been, mixed with flour, eaten as food. Some writers assert that hundreds of cart-loads are consumed every year by the inhabitants of the north of Sweden. From analysis, it does not appear to contain any positive

BERIBERI, ber-e-ber-e' .- A disease common in Cevlon and other parts of the East Indies, characterized by difficulty in breathing, weakness, stiffness, and a sen-sation of numbness in the lower limbs, a bloated appearance of the face, and dropsical swelling of the whole The disease commonly comes on slowly, and terminates in the course of three or four weeks; but sometimes it attacks suddenly, and destroys the patient in from six to thirty hours. The causes of this disease in from six to thirty hours. The causes of this disease are not well understood. It is generally supposed to arise from exposure to cold damp air, and the want of stimulating and nourishing diet. Great difference of opinion also exists as to the best mode of treating this disease, some regarding it as a disease of debility, and,

consequently, have recourse to stimulants; others, con-sidering it to arise from increased internal action, residering it to arise from increased internal action, resort to blood-letting, &c. This mode appears to be that most generally recommended. The chronic, paralytic affection, termed barbiers, also common in India, was, until recordly, confounded with this acute disease. Barbiers is a disease of nervous debility, and, therefore, to be treated with tonics, cordisle, and nutritive diet. It commences with weakness, trembling, and a pricking sensation of the legs, thighs, and arms. Loss of appetite, indigestion, and emaciation, soon follow, and at length, if the disease continues, the muscles become paralytic. become paralytic.

BERLIN PORCELAIN, ber-lin'.—A peculiarly hard white porcelain manufactured at Berlin, and much prized by chemists for its valuable properties. Tubes, capsules, crucibles, and other vessels used for chemical purposes, are made of a wonderfully thin and white variety. They do not crack whon heated, and remain intact under the action of the most powerful chemical agents. They replace platinum when required for the ignition of precipitates, containing easily-reduced metals which would destroy a platinum crucible. They are also of great value in testing, where the resulting

precipitate is small, but coloured.

BERLIN-WOLLWORK. (See EMBROIDERY.)
BERME, or BERM, berm (Fr. berme), in Mil., a piece of ground projecting horizontally from the foot of a rampart on the outside, forming a sort of pathway between the rampart itself and the scarp of the ditch surrounding the fortification. It is generally about surrounding the fortification. It is generally about three feet in width; if broader than this, it is called the chemin des rondes, and serves for the passage of troops from one part of the works to another outside the walls, or for officers when going their rounds to see that the sentrics and guard are doing their duty. Sometimes the berme has a low wall on the edge of the ditch, or a row of palisades sloping outwards. A broad berme tends to prevent the ditch from being filled with rubhish when the rampart is exposed to an enemy's fire; but it has its disadvantage in offering a place on which the assailing party may effect a lodgement, and plant their ladders for taking the place by escalade.

BERNARDINES, ber'-nar-dins.—An order of monks named after St. Bernard, a celebrated Franciscan friar of the 14th century, by whom the order was reformed, but not founded. Their origin dates from the 12th century, and they differ little from the Cistercians. (See CISTERCIANS.)

BERNICLE GERSE, ber'-ni-kl.—The bernicle geese are marine in their habits, and feed almost entirely on algon and grass-wracks (Zostera marine). Like the common goose, they are only winter visitors to our climate, and pass during the summer to the highest control of the common grass during the summer to the highest control of the contr northern latitudes. The bird owes its name to a ridi-culous notion. It was formerly believed (it can scarcely be said that the belief is to this day entirely abandoned) he said that the belief is to this day entriefy someoned that these birds were produced from the common beruacle, or harnacle, the latter originating, in their turn, from the fruits of a particular tree, whose branches dipped into the water. "There is," says Gerard (who lived in the reign of Queen Elizabeth), "a small island in Langshire called the Pile of Foulders (on the west side of the entrance into Morecombe Bay, about fifteen miles south of Ulverston), wherein are found the broken pieces of old and bruised ships, and also the trunks and bodies, with the branches of old and rotten trees cast up there likewise, whereon is found a certain spume or froth, that in time hardeneth unto certain shells in shape like those of the muskle, but sharper pointed, and of a whitish colour, wherein is contained a thing in form like a lace of silke finely woven, as it were, together; one end whereof is fastened into the inside of the shell, even as the fish of oisters and muskles are; the other end is made fast into the helly of a rude mass or lump, which in time cometh to the shape and form of a bird: when it is perfectly formed the shell gapeth open, and the first thing that appeareth is the gapeth open, and the first thing that appeareth is the aforesaid lace or string; next come the legs of the bird hanging out, and as it groweth greater it openeth the shell by degrees, till at length it is all come forth, and hangeth only by the bill. In short space after it cometh to full maturitie, and falleth into the sea, where it gathereth feathers, and groweth to a fowl bigger than a mallard, and lesser than a goose, which the people of

# Berry

Lancashire call by no other name than a 'tree-goose;' which place aforessid and all those parts adjoining do so abound therewith that one of the best is bought for three pence."

BEREY, in Bot. (See Bacca.)
BEREARII, ber-sair i-i, is a term used by writers of the Middle Ages to denote a kind of hunters who pursucd wild beasts. The derivation is doubtful; by some it is said to come from bersare, to shoot with a bow, by others from bersa, the sence of a park.

BERIH, berth, in Mar., the station in which a ship

rides at suchor; also an apartment where any number of the officers or ship's company mess and reside. In a man-of-war there is generally one of these between

every two guns.

BERTHOLLETIA, ber-tol-le'-ti-it (so named in honour of Berthollet, the French chemist), in Bot., a gen. of plants belonging to the nat. ord. Lecythidacea. The only species known is B. excelsa, a majestic tree, growonly species known is B. excelsa, a majestic tree, growing to the height of 100 or 120 feet, which forms vast forests on the banks of the Orinoco. The leaves of this plant are about two feet long and five or six inches wide. Its fruit is a round woody pericarp, filled with seeds or nuts, and so strong that it cannot be broken without a sledge-hammer. The seeds more or less approach a triangular shape, and hate hard wrinkled shalls. These sometime in fact they wall-known shells. These constitute, in fact, the well-known Brazil nuts of the shops, also known in commerce as Juva, Castanha, and Para nuts. They yield an oil well adapted for burning; but the 50,000 bushels imported annually into this country from Brazil are chiefly used as food. The kernels are said to be deliwhen quite fresh; but, unfortunately, they are apt to become rancid, on account of the quantity of oil they contain.

BERTL. (See AQUAMARINE.)
BERTLIANS, be-ril'-li-rius, in Eccl. Hist., a sect of heretics that arose in the 3rd century, and took their name from Bervlius, an Arabian bishop of Bozrah.
They held that Christ did not exist before Mary; but that a spirit, issuing from God himself, a portion of the divine nature, was united to him at his birth .- Ref. Mosheim's Ecclesiastical History.

BESTLERI, bes-ti-air'-i-i, men who fought with wild

beasts in the

Roman amphitheatre, who were exposed to them by a decree of They law. were different from the glafrom distors, who fought with each other. The bestiarii were regularly trained and paid for their services. and greatly increased during Empire. the

The illustration is copied from an ancient bas-relief. BESSEMBER'S PROCESS FOR REFINING IRON, bes'-se-mer.—This is a process patented by Mr. Bessemer in 1856, for converting pig-iron more rapidly into malle-able iron and steel. The ordinary methods for accomplishing this object were very slow and tedious; and air was admitted very sparingly to the metal. Mr. Bessemer, on the contrary, in his operations forces air into and upon the iron. In the first place, he conveys the liquid metal direct from the blast-furnace to a large covered wrought-iron vessel, lined with fire-clay; atmospheric air is then forced through the liquid iron by means of a fire-clay pipe passing through the vessel and dipping into the fluid metal. This pipe is conneeded with a hot blast; and, as the air passes when the iron, its oxygen comes in contact with the carbon the iron, its oxygen comes in contact with the carbon the iron, its oxygen comes in contact with the carbon the iron, its oxygen comes in contact with a lot blast; and, as the air passes when it is not blast; and carries them off. This is and other impurities, and carries them off. cooled. When hard, it is broken up and conveyed to a puddling-furnace, where jets of steam and air are fored into and upon the iron, when it becomes molten. for the day's consumption; and a buyo is there offered 256

#### Betel

The steam and air together act upon the metal, the oxygen converting the carbon into carbonic soid. The steam is decomposed and the hydrogen escapes, while the oxygen unites with the iron, forming oxide of iron, which is again decomposed, the oxygen uniting with the carbon to form carbonic oxide; while at the same time the iron is reduced to the metallic state. If there is any sulphur present, it is converted into sulphurous acid and sulphuretted hydrogen. Mr. Bessemer also invented a process by which he converted pig-iron into wrought-iron and steel in one operation. Although the principles of the process were right theoretically, the principles of the process were right theoretically, the invention did not prove advantageous at the cut set, for the reason that a great quantity of good iron was lost through oxidation. Ultimately, the process became perfectly successful. (See Ron and STERL.)

BETA, bo'-/a, in Bot., the Beet, a gen. of plants belonging to the nat. ord. Chenopodiacee, and charaterized by a 5-cleft perianth, five stamens inserted on a fleshy ring surrounding the ovary, and the fruit adhering to the calyx, and collected in clusters of two or three. The species are found in Europe, the north of three. The species are found in Europe, the north of Africa, and the western parts of Asia. B. vulgaris,

the common beet, grows along the whole coast of the Mediterranean, and is cultivated in European gardens for its sweet, tender, and dark-red root, which is chiefly used in England as a salad, but in France and Germany as a common table vegetable. It is also cultivated on a large scale in many parts of the world as a source of sugar; and it is believed at the present time that about 400,000,000 lbs. of beetroot sugar are

annually produced in BRETROOT.

Europe. (See SUGAR.)

The beet used for this purpose is considered to be a variety of B. vulgaris, and is known as the sugar-beet. The mangel-wurzel, so valuable as a field-crop for feeding cattle, is another variety, and is distinguished by botanists as B. rulgaris, var. campestris. The white beet cultivated in gardens for the sake of its

white beet cultivated in gardens for the sake of its leaves, which are used as a substitute for spinach, is also merely a variety of the same plant.

Better, be-tel.—The name usually given to a narcotic masticatory, used by the Malays and other Eastern races. It is prepared by rolling up long pieces of the betel-pubter (see Aurca) in the leaves of the betel-publer (see Curval). (see CHAYICA), previously dusted on one side with the quickline of calcined shells. When chewed, the betel promotes the flow of saliva, and lesseus the perspiration from the skin. It stains the mouth, teeth, and lips red; an effect which, though disgusting to Europeans, is considered ornamental by the natives. imparts an agreeable odour to the breath, and is sup-posed to fasten the teeth, cleams the gums, and cool the mouth. The juice is generally swallowed. The the mouth. The juice is generally swallowed. The narcotic effects of this masticatory have not been experimentally investigated by travellers. To one not accustomed to betel-chewing, the nut is powerfully astringent in the mouth and throat, while the quicklime often removes the skin and deadens the sense of taste. After a while it causes great piddiness. On those accustomed to use it, however, the betel produces weak, but continuous and sustained, exhilarating effects; and out continuous and sustained, exhilarating effects; and that these are of a most agreeable kind may be inferred from the very extended area over which the practice of betel-rhewing prevails. Professor Johnston believed that the coveted effect on the system is the result of the combined influence, first, of the constituents of the nut; second, of those of the fresh pepper; and third, of the substances which are produced or evolved in the mosth in consequence of the chemical science. in the mouth in consequence of the chemical action of the lime and of the saliva upon the ingredients of both nut and leaf. In Lucon one of the Philippines, Meyer found in every corner of the house a little box or dish,

## Bethesda

to every one who enters, just as a pinch of shuff or nips is in other countries. Travellers, and those who work in the open air, earry the buyos for the day in little boxes or bags. The preparation of the betel falls on the female members of the family, who, during the forenous may generally he seen lying on the ground forencen, may generally be seen lying on the ground making buyos. These are consumed very rapidly; for maning curos. These are consumed very rapidly; for every man who can afford it puts a fresh one in his mouth at least every hour. "We have no means," writes Professor Johnston, "of estimating the absolute Quantity of this nut which is consumed yearly by the Asiatic nations; but it must be very great. It is chewed by probably not less than fifty millions of men. If we allow to each chower ten pounds which the contract of the co If we allow to each chewer ten pounds-weight a year, which is less than half an ounce a day, this would give the enormous consumption of five hundred millions of pounds-weight every year! Only tobacco, among the narcotics in common use, is used in larger quantity than this."—Ref. Chemistry of Common Life.

BETHESDA, TO LIE AT THE POOL OF, be-thes'-da, is a

BREVENA, TO LIE AT THE FOOL OF, be-ther-dd, is a colloquial phrase in Germany, employed in speaking of theological candidates who are waiting for a living. BRINLEMILMITES, beth-te-mites, called also Starbearers, an order of monks that appeared in England about the middle of the 13th century. But little is known respecting them. They were distinguished by a red star having five rays, which they wore on their breast, in memory of the star which appeared to the wise men of the East. They had a settlement at Cambridge. Another order of the same name was founded on the island of Teneriffe, which has forty houses, chiefly in the Canary islands; but they are also to be found in the Spanish West Indies.

BETROTHMENT, be-trother-ment (Goth. traum, to

BETROTHMENT, be trothe' ment (Goth. traunn, to trow), is a mutual engagement or promise by a man and woman, with a view to a future marriage. The word and woman, with a view to a future marriage. The word literally denotes the giving one's troth, that is, true faith or promise. Among the ancient Jews, the betrothing was performed either by a writing or a piece of silver given to the bride. Frequently, the engagement was entered into very early in life, though the actual marriage did not take place till the parties were of a proper age, and generally a twelvemonth or more elapsed between the betrothment and the marriage. During this interval, the young people had liberty to see each other, which was not accorded to them before; and the woman was considered as the lawful wife of him to whom she was betrothed. The engagement could not be broken off by the man without a bill of could not be broken off by the man without a bill of divorce; and if the woman was unfaithful, she was treated as an adulteress. Betrothment amounts to the same with what is called by civilians and canonists sponsalia or espousale, sometimes desponsation, and by the French, flançailles. Betrothment is either solemn, the French, flançailles. Betrothment is either solemn, made in the face of the church, or private, made before witnesses out of the church. To betroth by giving arrha, or earnest, is called by Middle-Age writers subarrars. Betrothment being of the nature of a contract, is subject to the same laws and conditions as other contracts. It can only be recognized as valid between persons legally capable of entering into such a consequent and in viting of effected through force. an engagement, and is vitiated if offected through force, fraud, or intimidation. In Germany, where betroth-ment is still common, there are various laws in force ment is still common, there are various laws in force regarding it. The consent of the parents is always necessary if the parties are under age; but if the parents withhold their consent unreasonably, the permission of the judge may be obtained to enter into the contract. If the opinions of the parents are diverse, the law gives effect to that of the father. In some parts of Germany, the consent of the relatives and the research of witnesses are required to add the presence of witnesses are required to render the contract valid; in others, such a contract is not only invalid, but the parties to it are punishable. By the common law of Germany, however, betrothments are valid in every case in which consummation or consecration by the priest has taken place. The parents, in such cases, are not allowed to apply for a dissolution of the contract one of the contract of the contract. In such cases, are not anowed to apply for a dissolution of the contract, mor can they refuse their consent, except for highly important reasons. In case of refusal to fulfil the contract by marriage, the injured party is allowed as action at law, to campel its performance; but from the crils that result from unhappy marriages, the means resorted to to compel its fulfilment are never that the contract when the crils that the compel its fulfilment are never that the contract when the crime the compel is a short imprisonment. great,—usually a small flue or a short imprisonment.

## Bevel

The betrothment generally takes place in a small circle of relations and friends. In Russia, the betrothment now forms part of the marriage ceremony. In Eng-land, formal betrothments were usual down to the time of the Reformation. The ceremony is said to have consisted in "the interchangement of rings, the kiss, the joining of hands, to which is to be added the testi-mony of witnesses." Whoever, after betrothment, remony of witnesses." Whoever, after betrothment, refused to proceed to marriage, was liable to excommination, till that species of punishment was abolished by 26 Geo. II. c. 33. The only remedy now for the aggrieved party is an action at common law for breach of promise of marriage.

BRTING. (See GAMMG.)
BRTULA, bet'-u-la, in Bot., the Birch, a gen. of trees or shrubs belonging to the nat. ord. Betulacen. With the exception of B. antarctica, an evergreen shrub found in Terra del Fuego, all the species flourish beyond the tropic in the northern hemisphere. B. aba, the common birch, is one of the most beautiful of our forest trees, and is found in most of the northern parts of Europe and Asia. Under favourable circumstances it grows to the height of sixty or even seventy feet; but as it approaches both the northern and southern limits of its native region, it gradually decreases in size, and ultimately appears as a mere bush. The leaves are small, of an ovate-triangular shape, and doubly serrated. The bark is smooth and silvery white and the outer layers are therewed. white, and the outer layers are thrown off as the trunk increases in diameter. This tree yields useful timber for turnery, hoops, fish-barrels, cattle-yokes, and other articles in which lightness is of more importance than durability; the wood is also employed for making char-coal. The bark is valuable as a dye-stuff, and, being exceedingly tough, is turned to a variety of uses by the exceedingly tough, is turned to a variety of uses by the poor of Northern Europe. Light boats, or canoes, sre formed of it by the Russians on the Volga; it is sometimes employed instead of slates for roofing houses, sometimes twisted into ropes, and is even used for making hats, shoes, and drinking-vessels. The outer layers yield an oil which is much prized by the tanner; it is this which gives Russia leather its peculiar odour. In the spring the sap of the birch contains much sugar, and forms, when fresh, an agreeable beverage; when fermented, it constitutes what is called birch wine, a liquor employed medicinally in domestic practice for stone and gravel. The young twigs are in general use for besoms. In former days they were thought to be indispensable instruments of education, and, in the school-boy's mind, were ever associated with the Latin grammar. The graceful tree known as the weeping-birch, and which will be suggested to all by the last sentence, is generally regarded as a mere variety of of B. alba; but a few botanists view it as a distinct species, and name it *B. pendula*. *B. nigra*, the black birch of North America, yields a fine-grained valuable timber, and, like the common birch, a saccharine juice. timber, and, like the common birch, a saccharine juice. B. papyracea, the paper birch, is a native of the more northern regions of the same continent; it is remarkable for its tough bark, which is used by the Indians as substitute for paper, and for constructing cances, boxes, and baskets. B. lenta, another American apecies, commonly known as the cherry-birch, yields the timber called mountain mahogany: its bark is one of the sources of the volatile oil called oil of winter green. (See Gualtheria.) The bark of the Asiatic species, B. bhajapaltra, is used in India as paper, and for lining the tubes of hookabs.

BRIULACER. bet-ulai'see. in Bot., the Birch fam.

BETULACEE, bet.u-law-ee-e, in Bot., the Birch fam., a nat. ord. of dicotyledonous plants, in the sub-class Monochlamydeæ. All the species are either trees or shrubs. The flowers are unisexual, the fertile being in one cathin and the barren in another. In each, small scales take the place of a true calyx. The fruit is dry, indehiscent, and one-celled, with a single seed. There are but two geners, Betula and Alnus (which see), and about sixty-five species, almost all natives of the colder regions in the northern hemisphere. Many of these are very valuable either for their timber, or for their astringent, tonic, and febrifugal barks.

Between Decks (Ang.-Sar.), in Mar., signifies the space contained between any two whole decks of

a ship.

BEVEL, or BEVIL, bev'-el, a term used by builders to express a surface sloping from another, at an angle

greater or less than a right angle: thus, if the edge of a thick board or stone, in which the upper or lower surface and the surface of any of the eides are at right angles to each other, be taken off with a plane or any instrument, to present a new surface sloping at an abuse augle to either of the other curface, it is said to be borelled. The name is also given to the instrument with which carpenters and masons work surfaces which are required to slope at the same angle. In its which are required to slope at the same angle. In its simplest form it is a piece of wood, with a thin plate of steel working in a groove at one end, so that it may form any angle with the wood less than two right angles. The steel plate can be fastened with a tight-aning sorew when it has been brought to the required angle.—In Mach., cog-wheels, with bevelled edges, or bevelled gear, as they are termed, are used to transfer the motive power from one direction to another.

BETTRACE, bev-c-raj (Ital. beveraggio), a term spiled to all liquids which are used either to quench the thirst at multate the storage the thirst, stimulate the stomach, or cause a healthy internal action. There are several kinds of beverages; internal action. There are several kinds of beverages; such as cooling, refreshing, tonic, stimulating, &c. In the Middle Ages, beverage, beveragium, or biberagium, was the money given to a workman, over and above his ordinary wages, for the purpose of buying drink. The afternoon and evening potations at colleges were formerly called beverages; it was also a term applied to a treat upon wearing a new suit of clothers; and the

to a treat upon wearing a new suit of clothers; and the drink given by a prisoner upon entering a debtor's gaol was generally called a beverage, or garnish.

BEY. (See Brs.)

BY ENDER, be'-ze ko'-dex (Beza'a Codex), a celebrated manascript of certain books of the New Testament, presented in 1581, by Theodore Beza, to the university of Cambridge; whence it is sometimes also called Codex Cantabriciensis. It is a thick court called Codex Cantabrigiensis. It is a thick quarto volume, and contains the four gospels and the Acts of the Apostles, written in Greek, upon vellum, with a corresponding Latin text on every opposite page. In 1793 a facsimile edition of this codex was published, in two vois folio, under the editorship of Dr. Thomas Kipling, entitled "Codex Theodori Bezæ Cantabrigiansis Evangeliæ, et Apostolorum Acta complectens, quadratis literis Græco-Latinus." The text of this MS, deviates more from the received readings and ms. deviates more from the received readings and from the principal Ms authorities than any other, and in critical weight it ranks the lowest of the four leading Mss. The other three are the Codex Alexandrinus, in the British Museum; the Codex Valicanus, in the Vatican library; and the Codex Regins Parisiensis, in the Imperial Library at Paris. The Beza Ms. is very ancient. Dr. Kipling was of opinion that it must have been written before the 3rd century; but the general opinion now is, that it belongs to the latter end of the 5th or 6th century.—Ref. English Cyclopadia—Arts and Sciences.

BEZEN, be-rānt, in Numis., a gold coin struck by the emperors of Constantinople, deriving its appel-lation from Byzantium, the former name of that city. They were the only kind of gold coin current in Europe for a long period of time. It appears that there were for a long period of time. It appears that there were various kinds of bezants, differing in size, weight, and the quantity of alloy that was added. The common the quantity of alloy that was added. The common beyant of Constantinople was worth about nine shillings; it is often found in the form of a flat dish, with the head of our Saviour upon it. The name was afterwards given to gold coins struck in many European countries, and in England up to the time of Edward III. Silver bezants were also coined at Constantinople, similer in size to those of gold; and silver coins so called are mentioned in old records to have been current in this country in the reigns of Stephen and

current in this country in the reigns of Stephen and John. The only silver coins in the collections of numismatists known by this name are pieces of money struck at Censtantinople, about 1100, and at later periods.—Ref. English Cyclopadia.—Arts and Sciences, BEZANT, in Her., one of the nine roundlets; a circular charge representing a piece of gold, taking its mane from the old Byzantine coin so called. In blazoning armorial bearings in which these charges are found, the metal is not described, as the bezant is always or, or gold, and the name itself is therefore sufficient.

or spotted with a great number of besants. A grees beganty is a cross composed of besents.

beganty is a cross composed of begants.

BEZOAR STONES, be-sor (Persian, po-scalar, untidote to poison), concretions found in the stomachs
of various animals. They are brittle egg-shaped
masses, about the size of a small walnut, and sixmostly dark pive in colour. On being out open,
they present the appearance of a maleus surrounded
by concentric deposits. They occur principally in the
stomachs of oriental goats, deer, and antelopes, said
were formerly looked upon as possessing supermatural
properties. They cured all diseases, and acted as appidotes against every poison: and wore so mach sought properties. They cured all diseases, and acted as against every poison; and were so mach sought after as to be worth ten times their weight in gold. Themest valued of these was obtained from the wild goat of Persia, and was called the Lapis Besons Orientalis. They are found, more or less, in all herbitors, and sometimes occur in the stomachs of persons living much on farinaceous food. They contain litho-fellic and ellagic acids.

and ellagic acids.

Bugavan-Gità, ba'-ga-vad ge-ta' (i.e. Revelations of the Daity), is the name of a very celebrated religiophilosophical didactic poem, dating from about the lst century of the Christian ers, and which is interwoven as an episode in the great Indian epic poem of the Mahābhārata. It comprises a complete system of the religious philosophy of India. The best edition of the text, with a Latin translation, is that of A. W. von Schlegel (Bonn, 1846). There is an English translation of the work by Wilkins (London, 1785), and one by Thomson (1855); and a German translation by Peiper (Leipsic, 1834).—Ref. W. von Humboldt, Ueber die unter dem Numen Bhugavad-Gitá bekannte Bpisode des Mahābhārada. Berlin, 1827.

Mahabharata. Berlin, 1827.

seed-capsules and larger leaves of the native hemp employed for making the celebrated narreotic called Huschisch (which see). The Indian hemp is a species of the genus Cannabis (which see also).

Bi, bi (Lat. bis, twice), a syllable signifying twice or double, and used as a prefix in certain compound names; as biceps, two-headed; bicarbonate, a carbonate with two equivalents of carhonic acid to one of base.

Binanch Acip, bichsi-tik, in Chem., an acid which

BIDASIO ACID, bi-bar-ik, in Chem., an acid which requires two equivalents of a protoxide of a base to form a neutral salt, such as the pyrophosphoric, lactaric, and malic acids.

BIBBU. (See NECTANDEA.)
BIBBU. (See NECTANDEA.)
BIBBU., bi'-bel (Gr. ta biblia, the books), is the name first applied by Chrysostom, in the 4th century, to that collection of sacred writings which is regarded by Christians as the revealed word of God. These writings are divided into two parts,—the Old and the New Testament, the former containing 39 books, the latter 27. The Old Testament only is regarded as sacred by the Jews; but both the Old and New Testament are

held as sacred by Christians. The term testament is a translation of the Latin testamentum of the Vulgate, which, in turn, is a translation of the Greek word sig-theke, a covenant. In the New Testament, the Old Testament writings are designated as the Scripture, the Scriptures, or the Holy Scriptures. About a.p., 180, the term Holy Scriptures is used to include the Gospels; and Irenmus calls the whole collection of the books of the Old and New Testament the divine Scriptures and the Lord's Scriptures. The Old Testament is a name used by St. Paul (2 Cor. iii. 14), being a trans-lation of the Greek expression palais diatheks, old

covenant

The Old Testament,-The Jews divided the books of the Old Testament differently from the present method, so as to make only 22, and thereby to correspond with the number of letters in their alphabet. They divided mismatists known by this name are pieces of money struck at Constantinople, about 1100, and at later periods.—Ref. English Cyclopadia—Arts and Sciences.

BEZANY, in Her., one of the nine roundlets; a circular charge representing a piece of gold, taking its manie from the old Byzantine coin so called. In blazoning armorial bearings in which these charges are found, the metal is not described, as the bezant is are found, the metal is not described, as the bezant is reformed, and the name itself is therefore sufficient.

BEZINYY, or BEZINYZ, be-zdn'-te, in Her., a shield or charge is said to be bezanty when it is strewed three of these books were called the poetical books, or 238

truth; the rest, the five rolls, from being read, on our ain festivals in their synagogues, from manuscript olls. As to the arrangement of the different books, As to the arrangement of the different books was not only differed from the Christians, but are ane sews not only differed from the Christians, but are not even agreed among themselves. The arrangement followed by Protestants generally is that adopted by Martin Luther. The Old Testament was written in Hebrew, with the exception of certain later portions in Chaldee. Little is known of the history of the asored books previous to the time of the Jewish captaints. tivity. According to the command of Moses, "the book of the law" was "put in the side of the ark." It is probable that to the same sanctuary were consigned. as they were produced, the other sacred books. After the completion of the temple, Solomon directed that these books should be removed into it, and, also, that the future compositions of inspired men should be sethe future of mpositions of inspired men should be se-cured in the same place. On the capture of Jorusalem by Mehuchadneszar, and the consequent destruction of the tample, the autographs of the sacred books are apposed to have perished; but, doubtless, nume-rous copies of them existed at that time, some of which were carried by the Jews to Babylon; for we find Daniel (Dan. ix. 2, 11—18), when in captivity, we find Daniel (Dan. 12. 2, 11—13), when in captivity, referring to the law, and also expressly mentioning the predictions of Jeremiah, which he could not have done if he had not seen them. After their return from captivity, we are told that the people requested Ezra to bring forth "the book of the law of Moses, which the Lord had commanded to Israel" (Neh. viii. 1). Accordingly, Ezra is said to have collected as many copies of the sacred writings as he could and from them to have premared a correct edicould, and from them to have prepared a correct edi-From the time of Ezra, the Hebrew canon is generally considered to have been completed, and Josephus affirms that from the time of Artaxerxes down to his own day, no one had dured either to add to, or to take from, or to alter, anything in the sacred books. Great care was taken by the Jews to preserve the ac caracy of the sacred text, and from an early period they were in the habit of numbering the words and even letters of each book. In the Talmud a digest of Jewish laws compiled between the 2nd and 6th centuries, an enumeration of the various readings in different MSS. as well as the words and letters in the Bible, is given. When the Talmud was completed, the Masorites of Tiberias commenced their labours. They were named from masora, tradition, as their annotations were the oral traditions which had been handed down from previous centuries. They are said to have first divided the different books and sections into verses, and to have They marked invented the vowel-points and accents. the number of verses in each book, and the number of words and letters in each verse. They noted the verses where they thought something was forgotten, the words which they believed to be changed, the letters which they thought superfluous, the repetitions of the same verses, the different readings, the words which are redandant or defective, the number of times that the same word is found in the beginning, middle, or end of a verse, the different significations of the same word; such were some of the labours of the Masorites to in-sure the accuracy of the text. As to the value of the labours of the Masorites, biblical critics are much divided in opinion. Some maintain that we are greatly indebted to them for preserving the purity of the sacred text, while others are of opinion that they corrupted the text by substituting for the ancient and true reading of their forefathers, another more favourable to their prejudices, and more opposed to Christianity. general opinion, however, is, that they discharged their duties in a fair and conscientious manner. The oldest versions of the Hebrew Scriptures are the Samaritan Pentateuch, and the Septuagint or Greek translation. The former of these is supposed to date from about the time of the Sabyloniah captivity; for it is not likely that, after that time, on account of the eumity that existed between the two peoples, they would have translated and adopted the books of the Jews. The

to the Hebrew MSS. The Septuagint is said by so to the Hebrew East. Am reprungate when to have been so called from having been approximate Banhedrim, or great council of the Jews, who seventy in number. According to another seventy in the seventy in seventy in number. According to anomer aco Ptolemy Failadelphas, when founding his libra Alexandria, wished to have a copy of the Jewish and applied to Bleazer, the Jewish high-priest at. salem, for proper persons to translate the He Scriptures into Greek. Eleazer accordingly serelders from each of the twelve tribes, seventy-two in all,—whence the work was termed Septement, two all,—whence the work was termed Septement, there is no doubt that the version of the Septement was written at different times, and by different hands. The Pentaleuch was first tanels, and by different name. The Pentacetten was array translated probably in the reign of Ptolemy Lagus, or of his son Philadelphus, and it is allowed to have been done with great fidelity and accuracy. Next in point of excellence is the version of the Proverbs. The Pasims and the Prophets have been vary indifferently executed. The Septuagint version was in great esteem among the Jews in the time of Christ; and very many of the quotations in the New Testament are made of the quotations in the New Testament are made from it. Josephus, too, makes more use of the Sep-tuagint than of the Hebrew text; but at a later period, when the Christians employed the Septuagint, the Jews rejected it. Fragments of three Greek transla-tions of the Old Testament, all of, or mear the 2nd century of the Christian era, are preserved in the Hexaple of Origen, known as those of Aquila, Theo-dotion, and Symmachus, of which the first is the most valuable. The principal of the other early translations are the Nexago or Pachita (literal), from the Hebres are the Syriac or Peshito (literal), from the Hebrew, made about the end of the lat century, and embracing both the Old and New Testaments; the Coptic, from the Septinagint, probably about the 3rd century, and including the New Testament; the Ethiopic, from the Septinagint, probably in the 4th century, including also the New Testament; the Armenian, by Micerob, from the Septinagint, in the beginning of the 5th century; the Italia from the Septinagint, in the beginning of the 5th century; the Italic, from the Septuagint, in the lat or 2nd century, embraced also the New Testament,—but only fragments of it now exist; the Vulgate, which is the great authority with the Roman Catholics, was made from the Hebrow by Jerome, A.D. 300; the Gothic varsion of Ulphilas, of the 4th century, but of which only a part only has come down to us. From a belief in the absolute integrity of the Hebrew text, in consequence absolute integrity of the Hebrew text, in consequence of its supposed preservation from error by the Masora, it was not until the 17th century that any extensive collation was made of the various Hebrew MSS. Among the first to call attention to this subject was Louis Capell, who, in his "Critica Sacra," published at Paris in 1650, called attention to the differences that existed between the Hebrew and Samaritan Pentateuch, and between the Hebrew text and the Septuagint version. At length the necessity of a collation of Hebrew MSS, began to be generally acknowledged; and some attempte to that purpose were made by several subsequent editors of the Hebrew Rible. The several subsequent entires of the heavest hilled. The first great attempt made for that purpose, however, was that of Dr. Kennicott, commenced about 1760. The first volume was published in 1766, the second in 1780. The total number of Codices collated by or for Dr. Kennicott was 694, of which 634 were M88,.43 printed editions, and the remaining 17 were copies of the Talmud, rabbinical works, and collections of various readings. Of these, about 250 M8S, were colleted by Dr. Kennicott himself, and nearly 460 by his coadjutor M. Bruns, of the university of Helmstadt. Of these, some were collated throughout; others only Or these, some were constant inrongnout; others only in a few select passages, from being written in conformity with the same standard. In the opinion of Dr. Kennicott, fifty-one of these MSS, were from 600 to 800 years old, and 174 from 480 to 580. Soon after this, Professor De Rossi, of Parms, published his various readings of the Old Testament in 4 vols. 4to, entitled, "Varion Lectiones Veteris Testamenti ex the time of the Batylenian deptivity; for it is not readings of the Old Testament in 4 vols. 4to, likely that, after that time, on account of the emitty entitled, "Varim Lectiones Veteris Testamenti ex immensa Manuscriptorum editorumque Codicum contranslated and adopted the books of the Jews. The Samaritan Pentsteuch now extent is said to be a version from the earlier Hebrew Samaritan, into the more many of the MSS. collated for Dr. Kennicott, and modern Samaritan, and was made before the time of verified the extracts from them, besides examining numerous additional MSS, and editions examined by generally agreed that it is on the whole much inferior him amounts to about 1,300. Of the immense mass of

various readings which these colletions exhibit, multitudes are insignificant, consisting frequently of the omission or addition of a single letter in a word. omission or addition of a single letter in a word. They serve, however, to show the authenticity and integrity of the sacred text in all that constitutes the proper essence and substance of divine revelation,—its doctrines, moral precepts, and historical relations.

\*\*New Testament.\*\*—The books of the New Testament were originally written in Greek.

They were com-

posed at different times, and for different purposes. They must have for some time circulated singly, but when or by whom they were collected into one uncertain; it seems, however, to have been done by degrees, and that some books were much longer in being received into the canon than others. The first being received into the canon than others. The first evidence that we have of the existence of the collected books is in the Muratorian canon of the West, evidently written about A.D. 170. It is only a fragment, mutilated both at the beginning and the end; commences with a clear reference to St. Mark's gospel, and then passes on to St. Luke as the third, then St. John, the Acts, and the thirteen epistles of St. Paul. The epistle of Jude, the two epistles of John, and the Apocalypse of St. John, are mentioned in the text. The canon of the Peshito forms a remarkable complement to this catalogue. It includes the four gospels and the Acts, fourteen epistles of St. Paul, I John, 1 Peter, and James, omitting Jude, 2 Peter, 2 & 3 John, and the Apocalypse. Up to this point, therefore, 2 Peter is the only book that is not recognized as an apostolical and authoritative writing. (See Smith's Dictionary of the Bible, art. Canon.) The testimony of Eusebius as to the received books of the New Testament in his day is of value. He divides them into two classes, the acknowledged books and the disputed books. In the former class are the four gospels, the Acts of the Apostles, the fourteen epistles of St. Paul, I John, and I Peter; the disputed books he divides into two classes,—those which are generally recognized as authentic, and those which are considered spurious ; the former comprising the epistles of James, Jude, 2 Peter, and 2 & 3 John; the latter the Acts of Paul the Shepherd, the Apocalypse of Peter, and the Apotas Saepherd, the Apacatypse of Feter, and the Apacatypse of John (if not a work of the apostle). Down to the time of the invention of printing, the books of the New Testament were preserved in manuscript; but the vigilance produced by the constant controversies between the Catholics and heretics has served to maintain its general purity. Of the MSS. of the New Testament, upwards of 1,400 are known to scholars, and have been collated without any essential differences being found between them; numerous errors, however, had crept in, from the commutation of letters, transposition of words, seeing and hearing incorrectly, abbreviations, attempts at correcting the text or making it clearer. Modern critics reckon no fewer than 80,000 discrepancies in the various MSS. The oldest MSS. belong to about the 4th century, and are written in the uncial characters; the modern, from the 10th century downwards, are in the cursive characters. The most important MSS, are the Codex Alexandrinus, in the British Museum; the Codex Vaticanus, in the Vatican, at Rome; the Codex Regins Descriptions in the important library at Paris, and the Parisiensis, in the imperial library at Paris; and the Codex Bess, or Cantabrigiensis, in the library of Cambridge university. The first printed edition of the entire New Testament was that of the Complutensian Polyglot, published at the cost of the celebrated Cardinal Ximenes. It was commenced in 1502, and the printing of the book was finished in 1514, but the publication was delayed till 1522. Meanwhile, Erasregionation was delayed till forz. Alesindie, hras-ruas, in 1516, published his first edition of the New Testament. Stephens' first edition appeared at Puris in 1546. The first attempt at a critical edition was made by Bezz; and the first edition was published in 1565. The first truly critical edition is that of Dr. John 1565. The first truly critical edition is that of Dr. John Mill (Oxford, 1707), in which are gathered together 30,000 various readings. Bengel, Wetstein, Grizebach, and Scholz, followed in the same field. Scholz's first volume appeared in 1830, and the second in 1836; he describes no less than 674 different MSS., of which 331 were, for the first time, collated by himself.

English Bible.—It is probable that soon after the introduction of Christianity into this country, portions of the Scriptures were translated into the language of

the people. The earliest version of which we have my account is a translation of the Psalms into the Saxon language, by Aldhelme, or Adhelme, first bishop of Sherborne, about the year 706. A Saxon version of the property of the people was made by Egbert, bishop of Lindau. cuertorne, about the year 706. A Saxon version of the four gespels was made by Egbert, blahop of Lindiafern, who died 721. By some writers, Bede is easie to have made a complete translation of the whole Bible; but this seems doubtful, though he certainly did translate portions of it. King Alfred executed a translation of the Psalms, and Elfric, archbishop of Canterbury, is said to have executed a translation of the Pentauch and cartain other notions and Saxinton. the Pentateuch and certain other portions of Scripture, about 995. The first English translation of the whole Scriptures is supposed to have been made in the 13th ocriptures is supposed to have been made in the 13th century; and towards the end of the 14th century; one John de Trevisa, a native of Cornwall, is said to have made a translation of the entire Bible. This was, at any rate, done by his celebrated contemporary John Wickliffe, rector of Loughborough; in Leicesterahire. With the aid of various assistants, he, about the year 1380, translated the entire Bible from the Latin Vulgate into English. A complete addition of this translation. into English. A complete edition of this translation was published in 1851, at the Oxford University Press, under the editorship of the Rev. Josish Forshell and Sir Frederick Madden. The New Testament from this version had previously been published by John Lewis, a clergyman of Margate, in 1731, and by Mr. Baber, of the British Museum, in 1810. From the time of Wickliffe, the authorities of the English church did all they could to discountenance the circulation of the Scriptures in the language of the people; so that it was not till 1526 that a Bible or Testament was printed in English, and then only at a foreign press. William Tyndale resolved to accomplish this object, and, with this view, he went over to the continent. In 1526 he completed an English translation of the New Tests-In 1526 he ment, which was printed in two editions, one in quarto, the other in duodecimo. Copies of these were secretly conveyed into England, where they were immediately bought up and burned; but this only stimulated Tyndale to greater exertions, and enabled him to carry on his operations. He next proceeded to prepare a version of the Old Testament, and published a translation of the Pentatench and the book of Jonab. He did not, however, issue a complete translation of the Bible. The first English version of the whole Bible is that by Mark Consulation of the Whole School and the the Whole School an that by Marke Coverdale, a friend of Tyndale, and which was printed at Zunch in 1535, and dedicated to Henry VIII. It was favourably received by the court, and it was enjoined that a copy of this translation should be haid in the choir of every parish church in England, for every one to read at his pleasure. Re-prints of the edition were published in 1839 and 1847. prints of the edition were published in 1839 and 1819. The next English Bible, also printed abroad, is known as Metthew's Eible, from Thomas Matthew, the assumed name of the editor (John Rogers), also a friend of Tyndale. It was published in 1837, and the text is that of Tyndale and Coverdale, slightly altered. The Great Bible, or Cranmer's, so called from the preface being written by that prelate, was published in 1539: the text is Coverdale's revised. In the same year ap-peared the Traverner's Bible, by Richard Traverner, the text of which is based upon that of Matthew's Bible. The next important translation was the famous Geneva Bible, which appeared in 1557. During the reign of Mary, several of the more prominent Reformers took refuge in Geneva; among whom were Coverdale, Gilby, and Whittingham. They employed themselves in pre-paring a new edition of the Bible, accompanied with notes. From the strong leaning which it showed to the views of Calvin and Beza, it was long the favourite Bible of the English Puritans and the Scotch Presbyterians. This edition is frequently called the Breeches Bible, on account of the rendering of Genesis ii, 7, "and they sewed fig-tree leaves together, and made themselves breeches." The Bishop's, or Parker's Bible, so called from Matthew Parker, archbishop of Bible, so called from Matthew Farker, archbishop of Canterbury, who, with eight bishops, and several other scholars of reputation, revised the previous transla-tions, and compared them with the originals. This edition appeared in 1868. The Douay Bible, which is the Roman Catholic Version of the Scriptures, is a translation of the Vulgate: the New Testament was published at Rheims in 1882, and the Old Testament at Douay in 1609-10. King James's Bible, the one

still in universal use in this country, was prepared in the reign of James I. At a conference of divines at Hampton Court, in the beginning of 1604, for settling the peace of the Church, the importance of a new lation of the Scriptures was brought prominently constant of the scriptures was rought promently forward. It met with the approval of the king, and arrangements were at once made for carrying out the project. Fifty-four scholars, most distinguished for that kind of learning which this duty required, were scleeted for the work, and finally forty-seven of them undertook it. These were divided into six companies to each of which a certain portion of Scripture was These were divided into six companies, assigned. Each person of a company was to prepare a translation of the whole portion committed to that company, and these several translations were then revised at a general meeting of the company. When a company had in this way agreed upon their version, it was to be transmitted to each of the other companies, so that no part was to be without the sanction of the whole body. Two of the companies sat at West-minster, two at Oxford, and two at Cambridge. The final revision of the whole was conducted in London by two delegates from each of the six companies. These twelve scholars were occupied for nine months in the discharge of their critical duties. The work of translation and revision occupied from 1607 to 1610, and it lation and revision occupied from 1607 to 1610, and it came forth from the press of Robert Barker in 1611. The best evidence of the excellency of this translation is that it has remained in general use to the present time. Many are, indeed, of opinion that the time has now arrived when a new translation is necessary, and that, from our improved knowledge of the originals, and our better understanding of the general principles of translation, a greatly improved version would be the result; but such opinion has not yet met with any general response. There have, however, been many translations of particular books by private individuals. translations of particular books by private individuals.

BIBLE PROMIBITION.—The prohibition of the Bible to the laity, as held by the Roman Catholic church,

BIBLE PROWIEITION.—The prohibition of the Bible to the laity, as held by the Roman Catholic church, took its rise in the Middle Ages; for there is abundant evidence showing that it did not exist in the early ages of the Church. From the time that Gregory VII., in 1080, declared that the Latiu language should be the language of the Church, the Vulgate became the scripture text; and, consequently, the public use of vernacular copies of the Scriptures ceased. It was not, however, till 1199 that Innocent III., with a view to check the spread of the reformed principles of the Waldenses, prohibited the private possession or reading of the Scriptures without the permission of the Church. Similar prohibitions were issued at Toulouse (1229), at Beziers (1233), and at the synod of Oxford (1335), when the principles of Wickliffe were spreading. Since that time, numerous enactments of the Church have been made on this subject, one of the latest being that of Leo XII. (1824), in which he condemned Bible

BIBLE SOCIETIES are associations formed for circulating copies of the Holy Scriptures. Among the earlier and more important of these associations were the Society for Promoting Christian Knowledge, established in 1698; the Society for sending missionaries to India, established in Denmark 1705; the Society for Promoting Christian Knowledge in the Highlands and Islands of Scotland, formed in Edinburgh 1709; the Moravian Missionary Society, founded in 1732; the Book Society for Promoting Religious Knowledge among the Poor, formed in Londou 1750; and the Naval and Military Bible Society, established in the year 1780. The efforts, however, of all these societies were still far from being equal to the object in view. The first idea of establishing the British and Foreign Bible Society aroas from the great scarcity of Bibles in Walse; and the earliest stops towards its formation was convened; and it was then resolved that a society as some convened; and it was then resolved that a society be formed, under the designation of the British and Foreign Bible Society, the sole object of which shall be to saccurage a wider diffusion of the Holy Scriptures.

gious opinions was also named to carry out the arrange-ments. One of the rules then passed was that the govern-ing body was to consist of 36 laymen, of which 15 were to be churchmen, 15 dissenters, and 6 foreigners resident in or near the metropolis. Every dergyman or dissenting minister who is a member of the society is entitled to attend and vote at any of the meetings of the committee One of the fundamental rules of the society was, that it was to promote the circulation of the Scriptures, without note or comment, both at home and abroad. This subsequently gave rise to several controversies; at one time certain divines of the Church of England insisting that the Prayer-book ought to be given along with the Bible; and, more recently, the circulation of the Apocrypha on the continent, along with the canonical books of Scripture, led to a prolonged controversy. (See APOCRYPHAL CONTROVERST.) The British and Foreign Bible Society soon became the parent of numerous other associations for the circulation of the Holy Scriptures; and at present there are in connection with it about 700 auxiliary societies, a like number of branch societies, and about 2,000 associations. The of branch societies, and about 2,000 associations. The income of the society for the year ending 31st March, 1861, was £250,850; of which £147,164 was derived from subscriptions, donations, legacies, interest, &c.; £82,009 from receipts for Hibles, Testaments, and drawbacks of duty; and £777 from special contributions to the Chimese New Testament and India fund. The total expenditure for that year was £165,462; and the number of Bibles, or portions of Bibles, issued from London during that year was 1,787,398. From the establishment of the society down to 1861, they had issued no fewer than 39,315,226 copies of the Bible, or portions of it. The Society for Promoting Christian Knowledge ranks next to the British and Foreign Bible Society in its efforts to diffuse copies of the Holy Scriptures, although its operations are not confined to that object. The average annual issue of this society is about 150,000 Bibles, 75,000 New Testaments, and 300,000 Common Prayer-books; pesides other books and tracts amounting to about 4,000,000. Like the Bible Society, it issues translations of the Scriptures in foreign languages, and has its agents for promoting the diffusion of the Scriptures abroad. The Edinburgh Bible Society was instituted in 1809. Its average annual income is about £3,000; and it distributes annually about 3,500 Bibles, a large portion of which are in the Gaelic language, and are circulated in the Highlands and islands of Scotland, and in the colonies. In the United States of America the first Bible Society was that established at Philadelphia, in 1808. In 1817 the American Bible Society was formed at New York. It has now about 1,200 auxiliary societies in all parts of the United States, and has an annual income averaging about £80,000; of which rather more than one-half is derived from the sale of Bibles and Testaments; the rest from donations, col-Bibles and Testaments; the rest from donatons, coincident, so, it issues annually upwards of 700,000 Bibles, Testaments, or portions of Scripture. Its head-quarters, the Bible-house, is a large and magnificent building, erected by public subscription. On the continent of Europe, the first foreign Bible society was that formed at Nürnberg, 1804; but the seat of its operations was subsequently transferred to Basel. In 1805 a Bible society was formed in Berlin, which subsequently became merged in the Bible Society of Prussia, established in 1814. This is the most flourishing of the German societies; and it has issued upwards of 2,000,000 copies of the Bible and New Testing of the Bible an tament. In 1813, the Russian Bible Society was establighed in St. Petersburg. It carried on its operations with great activity: but it was suppressed, by order of Nicholas, in 1826. A Protestant Bible society has since been formed for the purpose of supplying Protestants in Bussia with the Holy Scriptures. In Paris, a society was formed in 1818, and still exists, under the name of the French Protestant Bible Society. There are similar societies at Stockholm, Copenhagen, Hamburg, Lubeck, Dresden, Frankfort-am-Main, Stuttgart, &c.

BIBLIA PAUPREUM, paw'-pe-rum (Lat., Bible of the poor).—Before the invention of printing, a copy of the Bible being rare and expensive, the principal subjects of the Old and New Testament were represented in some forty for fifty pictures, with a short explanation of

# Biblical Antiquities

texts of Saripture undermeath each. This was called the "Bhlis Pauperam." It and a similar, but more extended work, called "Spaculum Humans Salva-kimis" (the Mirror of Human Salvation), in a great measure took the place of the Bible in the Middle Ages, and were the chief text-books need by the clergy in addressing the people. Many copies of these works at the control of the copies of these works atill exist.

BUBLICAL ABRIQUITIES, OF BUBLICAL ABCHROLOGY, BIBLICAL ABTRIQUEITES, OF BIBLICAL ABCHROLOGY, wheelvelvels, is the name given to that science which treats of the antiquities, the political constitution, customs, manners, &c., of that people with whom the Boly Surpaura originated, or those to whom it refers.

A knowledge of biblical archwology is indispensably the statement of the surparate accessary to a right understanding of many parts of Scripture. Though this study primarily regards the Scripture. Though this study primarily regards the Jewisli people, yet the manners, customs, &c., of the aeighbouring Semitic nations necessarily form part of it. The principal sources of this knowledge are the Old and New Testaments, the books of Josephus Oldwah antiquities and the wars of the Jews, the writings of Philo, the Talmud and the Rabbinical works, the Greek, Roman, and Arabian writers, ancient monuments, and the works of modern travelworks, the Green, Molnan, and the works of modern travel-lers. For the first work on Hebrew archeology we are indicated to Dr. Thomas Godwyn, whose book, "Moses and Agron, or Civil and Ecclesiastical Rites used by the Ancient Hehrews," appeared at Oxford in 1616. The Germans have particularly distinguished themselves in this department, and among the more recent works that have appeared, are Warnekros, "Entwurf der hebr. Alterthiuner" (Weimar, 1781, 5th edit. 1832); Jahn, "Bibl. Archæologie" (5 vols. Vienns, 1796—1805); Bauer, "Lehrbuch der hebr. Alterthiuner" (Leipsic, 1797); De Wette, "Lehrbuch der hebr. Alterthiuner" (Leipsic, 1797); De Wette, "Lehrbuch der hebr. Jid. Archæologie" (Leipsic, 1814, 2nd edit. 1830); Rosenmiller, "Handbuch der Bibl. Alterthumskunde" (Leipsic, 1823); Winer, "Bibl. Realwörterbuch" (5rd edit. Leipsic, 1847). In English, there are a translation of an abridgment of Jahn's "Biblical Archæology," by Professor Upham (1827); Horne's "Introduction to the Holy Scriptures" (vol. 3); Kitto's "Pictorial Bible;" and the cyclopædias of Kitto, Smith, Eadio, &c. Beblical Certificats is that science which concerns selves in this department, and among the more recent

BIBLICAL CRITICISM is that science which concerns itself with the origin, history, and present state of the original text of Scripture. It comprises a critical knowledge of the languages in which the Scriptures were originally written; the composition, collection, and preservation of the different books; the age, characteristics of the composition of the different books; the age, characteristics of the control of the different books; the age, characteristics of the control of the different books; the age, characteristics of the control of the different books; the age, characteristics of the control of the different books; the age, characteristics of the control of the different books; the age, characteristics of the control of the different books; the age, characteristics of the control of the c racter, and relationships of the various MSS.; the various readings; and the different philological and instorical means to be employed, in order to determine what the text was as it proceeded from the different permen. Its tendency is not, as is said by some, to weaken or destroy the foundations of Christianity, but, weaken or destroy the foundations of Christianty, but, on the contrary, to strengthen and increase them, by proving the authenticity and genuineness of the Holy Scriptures. It is divided into two kinds, a lower and a higher,—the former merely concerning itself with the words as they stand in the various MSS. or printed the words as they stand in the various also, or printed texts; the latter implying the execuse of the reason in judging of the texts from the context, from the circumstances of the writers, &c. Of these two, the former is the more important and reliable; the latter, as being more open to conjecture, is liable to be abused. Biblical criticism is of comparatively recent origin. It scose, partly at least, in consequence of the controversies in which men became involved on religious subjects, and the necessity of having a correct standard to which to refer. It is utterly impossible for human cantion and diligence to guard against the slightest departure from an author's original words in transcribing, and, consequently, in the course of many centuries, and by being frequently transcribed, numerous different readings had acreen, which it became necessary to decide between, and to weigh the evidence by which they were respectively supported. The authen-tic reading must be determined by authorities, and these authorities are judged of by certain rules. Bibthese authorities are judged of by certain, rules. Bib-lical criticism, then, in its strict and proper sense, comprehends "the sum and substance of that know-

# Bibliography

for before we try to secertain the meaning of an author, we should be careful to see that we have his words.
"There are five sources," says Dr. Davidson, "from which criticism derives all its aid in ascertaining the changes that have been made in the original text of changes that have been made in the original value of the Bible, and replacing authentic readings sachuded by them." These are—1. Ancient versions of the Sacred Scriptures; 2. Parallels, or repeated passages; 3. Quotations; 4. MSS., or written copies; 5. Criticial conjecture. (See Bible.)—Ref. Dr. Davidson's Treaties on Biblical Criticism; Porter's Principles of Textual Criticism.

BIBLICAL INTERPRETATION, OF SACRED HERMENEU-TICS, is the science of teaching or expounding the meaning of the Sacred Scriptures. When the inter-TAUS, is the science of teaching or expounding the meaning of the Sacred Scriptures. When the inter-preter has obtained a pure text by the results of criti-cism, he enters upon another and a more important field,—that of its interpretation. He has now a twofold. duty to perform : first, to associate in his own mind with the terms, the exact idea which the Spirit intended they should symbolize; and, secondly, to excite the same idea in others by means of spoken or written signs. He has to apprehend the meaning of Scripture, and to exhibit it when apprehended, so as to be intelligible. Biblical interpretation is either grammatical or historical,—grammatical, when the meaning of the words, phrases, and sentences, is made out from the usus loquendi and the context; historical, when the meaning is illustrated and confirmed by historical arguments, which serve to evince that no other sense can be put upon the passage, whether regard be had to the nature of the subject or to the genius and manner of the writer. (See HERMENEUTICS.)-Ref. Davidson's Sucred Hermeneutics.

BIBLICISTS, or BIBLE DOCTORS, bib'-li-sists, in Eccl. Hist., was a name given, in the 12th and 13th centuries, to those doctors or learned men that made the Holy Scriptures the chief subject of their study and the text of their lectures. The scholastics, on the other hand, brought all the doctrines of fairh, as well as the principles and precepts of practical religion, under the dominion of philosophy. The scholastics came to be regarded as men of much more ability and ingenuity than the biblicists, and their lectures were flooked to and admired by the young; and, consequently, the Bible doctors were despised. They had few scholars, and had not even a stated time for reading their lectures in any of the famous European universities. The scholastic theology, with its triling subtilities, prevailed in all the universities and colleges of Europe down to the Reformation.

of Europe down to the Reformation.

Bibliography, bib-li-og'-rafe (Gr. biblion, a book, graphe, a writing), may be defined to be the science of books. Anciently, the term bibliographia denoted the writing or transcription of books, and a writer or copyist was termed bibliographos. When the transcribing of books ceased, after the introduction of printing, bibliography came to signify an acquaintance with ancient manuscripts, and a skill in the deciphering of them. The term was not used in its present signification till about the middle of the 18th century, and it was first introduced in France. Bibliography (for which bibliology or bibliograps would be more appro-priate) denotes a knowledge of books, with reference to their constituent parts, their different editions and degrees of rareness, their subjects, authors, classes, &c. There are some who would include under bibliography many other branches of knowledge, indeed, so many as to render it impossible to lay down any limits for the science at all. The sphere and duties of the bibliographer are well and clearly laid down in the following extract. "It is the business of the bibliofollowing extract. "It is the business of the bibliographer, then, to trace the history of books in regard to their forms and other constituents, and consequently. to trace the beginnings and progress of typography. It belongs to him in a particular manner to mark the differences of editions, and to point out that edition of every book which is esteemed the most correct and valuable. In the case of books published anonymously or under feigned names, it is his business to indicate the names of their real authors, in as far as the discoveledge which enables us to discover a wrong reading, to remove it from the text, and to obtain, as nearly as so. All remarkable facts attaching to the history of possible, the original words of the Bible." It is distinct from interpretation, but it forms the basis of it; ness, their having been condemned to the flames, or sup-

gressed, belong to the province of hibliographical in-quiry. Further, every one who engages in any particu-lar line of study must, of course, wish to know the books that have been published in regard to it, or in segard to any particular point that interests his surjosity; and it is the business of the bibliographer to furnish this most useful species of information; in other words, the compilation of catalogues of those books which have appeared in the various branches of knowledge, constitutes another department or bibliography. It is by means of such catalogues that the student comes to know what has been written on every part of learning; that he avoids the hazards of encountering difficulties which have already been cleared; of discussing questions which have already been decided; and of digging in mines of literature which have already been exhausted." (Art. Bibliography, by Macvey Napier, in Encyc. Brit.) The number of bibliographical works that have appeared in our own and other countries are so numerous that we can only afford to notice a few of the principal of them. One of the earliest attempts to present a complete survey of printed literature was made by Conrad Gesner, whose "Bibliotheca Universalis," in I vol. folio, appeared in 1545. The works are arranged according to the names of their authors; but it is limited to works in Greek, Latin, and Hebrew; so that even in his day it could not be said to be universal. The "Bibof Dr. Robert Watt of Glasgow is. liotheca Britannica" with all its imperfections, a most meritorious and use ful work. It was published in 4 vols. 4to (Edinburgh, 1824), in two of which the works are arranged alphabetically, according to their titles, and in the other two according to their authors. It professes to be "a universal catalogue of all the authors with which this country is acquainted; embracing every description of authors, and every branch of knowledge and litera-ture;" and it also gives a large number of works in other languages. The other labourers in this field of literature, however, have generally confined themselves literature, however, have generally confined themselves to books written upon one particular department of knowledge, to works belonging to a particular period, or issuing from a particular press; to anonymous or pseeddonymous works, or to rare or curious books. Of these we may mention Lownde's "Bibliographer's Manual of English Literature," giving an account of rare, curious, and useful books, 4 vols. 8vo, London, 1834 (a new and improved edition of this work is in 1834 (a new and improved edition of this work is a course of publication, under the editorship of Mr. H. G. Bohn); Darling's "Cyclopædia Bibliographica," a G. Hohn); Daring's "Cyclopædia Bibliographica," a library manual of theological and general literature and guide to books (Loudon, 1857-8); "A Critical Dictionary of English Literature and British and American Authors," by S. A. Allibone, 1 vol. 8vo (Phi-ladelphia, 1859); Horne's "Manual of Biblical Bibliography;" Dibdin's "Library Companion," 1824; Epune's "Manuel du Libraire et de l'Amateur des Livres," 4th "Manuel du Libraira et de l'Amateur des Livres," 4th edition, 5 vols. 8vo (Paris, 1842-44) (a uve and enlarged edition of this most valuable and useful work is now in course of publication); Querard's "La France Litteraire," 10 vols. (Paris, 1827-42); De Burc's "Bibliographie Instructive, ou, Traité de la Councissance des Livres rares et singuliers, contenant un Catalogue raisonné de la plus grande partie de ces livres précieux contenant un cutalogue raisonné de la plus grande partie de ces livres précieux raisomó de la plus grande partie de ces livres précieux qui out paru successivement dans la République des Lettres depnis l'invention de l'imprimerie," 7 vols. 8vo (Paris, 1763-8); M. Barbier's "Dictionnaire des Ancoymes et Pseudonymes," 4 vols. 1806-9; Ebert's "Allgemeines bibliographisches Lexikon," 2 vols. (Leipsic, 1821-30) (an English translation of this work has appeared in 4 vols. 8vo, Oxford, 1837); Heinsins' "Allgemeines Bicherlexikon," with supplements, 11 vols. (Leipsic, 1812-52); Ersch's "Handbuch der deutschen Literatur," 2nd edition, 4 vols. (Leipsic, 1822-40) (3rd edition, by Geissler, 1845); Vater's "Literatur der Grammatiken Lexika, und Wörtersammlungen aller Sprachen der Erde," 2nd edition (Berlin, 1847). (Berlin, 1847). BIBLIOMANCY, bib-li-o-man'-ae (Gr. biblion. a book

and manicia, divination), an attempt to gau an insight into futurity by opening the Bible and taking the passage which first offers itself as a means from which guidance or advice may be derived with regard to any vorldly matter about which the diviner may be in doubt Some practised it by going into a place of worship, and 263 taking the first verse of Scripture that might be a after their entrance. The practice of this art after their entrance. The practice of this art was prohibited by some of the councils of the Church in the 5th and 6th centuries. It was introduced into E land about 1070, and was much in vogue with the fam tic enthusiasts that were found among the troopers of Cromwell and the soldiers of the parliament, who must this unsatisfactory method of procuring what the imagined to be the divine approbation or disapprova imagined to be the drivine approbation or disapproval of their plans with reference to the most trifling matters in every-day life. Another method of divining by selecting passages at random from a book, was the Sortes Virgilians, in which a copy of the works of the Latin poet Virgil was used instead of the Bible.—Exf.

Latin poet Virgil was used and the Chambers's Encyclopadia.

Bieliouania, bib-li-o-mai'-mi-d (Gr. biblion, and mania, madness,—book-madness), is a word recently formed from the Greek, to denote a passion for the posterior of the posterior and curious books. The true bibliomatic response and curious books. session of rare and curious books. The true bibliom nise is not guided in his selection of books by their me utility or the value of their contents, but rather by some accidental circumstances connected with them. With him, rarity is what gives its chief value to a book; so that he is ever scarching after books of which only a few copies have been printed, or are known to exist,—early editions, works that have issued from a particular press, printed in a particular manner, on veilum or on large paper,—books bound in a particular on veilum or on large paper,—books bound in a particular way by a particular binder. The editions of the classics by the Elzevirs and the Fouliess are much prized; of the Italian classics, by the Academy della Crusca; the books printed by the Elzevirs and Aldus; there have been a priced by the Elzevirs and Aldus; those bound by Deromo, Bozerian, Lewis, or Rayne.
At the sale of the library of the duke of Roxburghe, in 1812, a copy of the first edition of Buccacio's "Decameron," published by Valdarfer in 1471, was sold for the enormous sum of \$2,280. This led to the formation of the Roxburghe Club, for the printing of rare or hitherto unedited books, the members of which agreed to dine together annually on the anniversary of the sale of the Boccacio. (See ROXBURGUE CLUE.) Dr. Dibdin, in his "Bibliomania; or Book-madness, containing some account of the history, symptoms, and cure of this fatal disease," after giving an account of the eminent book-collectors who have fallen victims to it, describes, as its symptoms, a passion for-1. large-paper copies; 2. uncut copies; 3. illustrated copies; 4. unique copies; 5. vellum copies; 6. first editions; 7. true editions; 8. black-letter editions; and prescribes for its cure—1. reading useful works; 2. reprints of scarce and valuable works; 3. editing our best ancient writers; 4. erecting of public institutions; 5. encouragement of bibliography.

BIBLIOTHECA, bib-li-o-the'-ka (Gr. biblion, and theke,

a repository), properly signifies a library, or reposi-tory of books. In literature, it denotes a treatise giving an account or list of all the writers on a vertain giving an account or list of all the writers on a vertain subject: thus, we have bibliothecas of theology, law, philosophy, &c. There are, likewise, universal bibliothecas, which treat indifferently of all kinds of books; such as Watts's "Bibliotheca Britannica;" also, select bibliothecas, giving an account of none but authors of reputation. (See BIELIOGRAPHY.)

BICAPSULAR, bi-kip'-su-law (Lat. bis, twice, capsula, a capsule), in Bot., having two capsules containing seeds to each flower.

seeds to each flower.

BICAEBURETTED HYDROGEN, bi-kar-bu-rat'-ted, -Olefiant gas. Also a name applied by Faraday to oil

(See CARBON.)

BICE, or BISE, bise (Ang.-Nor.), in Paint,, a pale-blue colour, which is prepared from the Lapie armenius (smalt), and is inclined to be sandy. Bice bears the temant, and a inclined to be sandy. Dice bears are best body of all bright blues used in common work, but requires good and careful grinding, and is, after ultramarine, one of the best of colours. A green, formed by mixing the blue with orpiment, bears the same name, as do also certain compositions of indigo and verditer with chalk.

BICEPS, bi'-seps (Lat. bis, twice, caput, a head), in Anat., is a common name applied to several muscles of the human body, from their having two distinct origins or heads. The principal of these are the biceps flexor cruris and the biceps flexor outlit, the former situated on the hind part of the thigh, the latter on the fore part of the os humeri.

BICKTER, be sailer, a castle and village in the neigh-bourhood of Paris, situated on a hill, and commanding one of the finest prospects of the capital, of the course of the Seine, and of the environs. Louis XIII. erected the castle for the residence of invalids. When Louis XIV. afterwards built the Hôtel Royal des Invalides, Biother became a great hospital, for which it is well adapted by its healthy situation. Water alone was wanting in its ricinity; to obtain which a well was dug in the rock. Bicêtre contains, also, a house of correction (maison de force) for dissolute persons, thieves, swindlers, &c. Since the revolution of 1703, a prison has been erected for those criminals condemned to has been erected for those criminals condemned to the galleys, who are afterwards sent to the public dockyards. Both in the prison and in the house of correction are shops for the grinding of glass, and for other kinds of work in which the prisoners are usefully employed. In the hospital, several hundred beds are allotted to aged patients. None are admitted under the age of 70 years: they are attended with the greatest care, and spend their leisure in the construction of little toys of wood or bone. Bicotre also contains a large hospital for incurable madmen.

Broowers history in Clast the and corner a horn), is

BICORNIS, bi-kort-nis (Lat. bis, and cornu, a horn), is a term sometimes applied in Anat. to the hyoid hone, from its having two processes like horns. Formerly, it was also applied to muscles that had two terminations.

Browsfires, or Browsfirmari, bi-kus'-pids (Lat. bis, and cuspis, a spear), in Anat., is applied to the two first pairs of molars in each jaw, from their having two spearlike tubercles.

BIDAL, or BIDALE, bid'-al (bid and ale), an ancient custom in England, by which friends are invited to drink ale at some poor man's house, and there to contribute something to his relief.

BIDDING PRAYER, bid'-ding. - It was part of the duty of deacons in the early Christian church to act as monitors and directors of the people in the exercise of their public devotions; hence they made use of certain forms or words to give the worshippers or hearers notice when each part of the service began. Bishop Burnet informs us that before the Reformation, when the priest had announced his text, he called on the people to go to their prayers, telling them what they were to pray for. "Ye shall pray," says he, "for the king, for the pope, for the holy Catholic church, &c." When this was done, the people repeated their prayers, counting them upon their beads, in perfect silence, the priest kneeling down likewise and saying his. The rising of the priest was the signal for all to cease their devotions, and the sermon was then proceeded with. The 55th canon of the Church of England enjoins that before all sermons, lectures, and homilies, the preachers and ministers shall move the people to join with them in prayer in a certain form. This form is known as the in prayer in a certain form. in prayer in a certain form. This form is known as the bidding prayer, or bidding of prayer, because in it the preacher is directed to bid the people to pray for certain specified objects. It is now rarely used, the practice of reading a collect or some short prayer before sermon being generally substituted for it. The form "Let us pray," repeated before several prayers in the English Liturgy, is taken from this practice of the early Church.

Bella's Comer, be'-la's (Gr. kome, hair), a comet discovered in the month of February, 1826, by a Prussian named Biels, at Josephstadt, in Bohemia. It accomplishes its elliptic revolution round the sun in rather more than six years and a half. It approaches the earth's orbit more closely than any other cometary body that has yet been observed, passing through the descending node of its own path, at a comparatively short distance from the orbit of the earth, and, in consequence, a collision between the comet and the earth was very much feared at one time, until careful calculations of the comet's orbit were made, and all alarm on the subject shown to be groundless. In 1846 the comet was observed to be separated into two parts, the cometwas observed to be separated into two parts, which travelled in company, at a distance of about 55,000 miles apart. It was not seen in its perihelion assage in 1279, as the circumstances attending its motion were unfavourable for its observation; but this also occurred in 1839, when it passed without notice. When last observed, in 1852, the two fragments into which it had been divided by some inexplicable means, were plainly noticed travelling onwards through 2641

space, at the same relative distance from each other as in 1846.—Ref. English Cyclopadia.—Arts and Beiences; Lardner's Handbook of Astronomy.

BIRMIAL, bi-en'-ni-ûl (Lat. bis, twice, annus, year), in Bot., a term applied to a plant which springs from the seed one year, but does not flower and seed until the second year, when it perishes. The biannial root is commonly enlarged at the close of the first season, by an accumulation of nutriment intended for the support of the plant during its flowering and fariting support of the plant during its flowering and fruiting. The carrot or the turnip is a familiar example of such

BIFFIN, bif'-fin, an apple baked slowly and pressed at. Norfolk is celebrated for it.

flat, Norfolk is celebrated for it.

BIGAMY, big-a-me (Lat. bigamia), in Law, is an offence against the holy state of matrinkuy, and consists of a second marriage, having a former husband or wife still living. Such second marriage is simply or whe sun living. Such second marriage is simply void and a mere nullity, by the ecclesiastical law of England; and yet the legislature has thought it just to make it felony, by reason of its being so great a violation of the public economy and decency of a well-ordered state. By the laws both of ancient and modern Sweden, it is punished with death. With us, the statute 9 Geo. IV. c. 31, makes the offence punishable with penal servitude for seven years, or imprisonment with or without hard labour for not more than two

BIGHT, bile (from the Sax. bygan, to bend), the double part of a rope when it is folded, in contradis-

tinction to the end.

BIGNONIA, big-no'-ni-d (named after the Abbé Bignon, librarian to Louis XIV.), in Bot., the Trumpetflower, the typical gen. of the nat. ord. Bignoniacea. The species are trees or shrubs, usually of a climbing habit, and furnished with tendrils. The leaves are opposite, and generally ternate, pinnate, or conjugate. The flowers are mostly in terminal or axillary panicles. The corollas are trumpet-shaped, and are coloured the coronas are trumper-snaped, and as the variously, white, yellow, orange, purple, or rose. All the species are magnificent plants when in blossom, and have long been cultivated by florists. They are, and have long open cultivated by floriate. They are, with few exceptions, too delicate to withstand our climate, and will only grow freely in stoves. From the leaves of the species B. chica, the Indians of South America obtain a red dye called chica, or carajura, which they use for painting their bodies and their arrows. This chica must not be confounded with the

arrows. This chica must not be confounded with the beverage of the same name. (See Zea.)

BIGNONIACEM, bij-no-ni-ai'-se-e, in Bot., a nat. ord. of dicotyledonous plants, in the sub-class Corolligitora. They are usually trees or shrubs, often twining or climbing; rarely herbs. They flourish in the hotter parts of Asia, Africa, and America, being unknown in Europe except in a cultivated state. The chief interest of these nearts lies it their heartful for the parts lies it their heartful for more therest. of these plants lies in their beautiful trumpet-shaped There are 44 genera and 450 species.

BIGOT, big'-ot, a word applied to a person perversely and obstinately wedded to some practice or opinion, but especially to one who adheres with vehemence to any peculiar notions or extraordinary dogmas upon questions of religion. According to Camden, the use of the word dates from the time when Gisla, daughter of Charles the Foolish, was given in marriage to Rollo, duke of Normandy. When Rollo had received the investiture of the dukedom, he was desired to kiss Charles's foot; but he refused to comply, and on his friends urging him to submit to the ceremony, he replied, in the English tongue, "Ne se, by God!" for which the king and his courtiers derided him, and, repeating his answer with imperfect pronunciation, called him bigot. After this occurrence, the Normans were ordinarily called bigods, or bigots.

BIKH. (See A CONITUM.)

BILDERNY. (See Vaccinium.)
BILBORS, hill-lose, long bars or bolts of iron, with
shackles sliding on them, and a lock at the end, used
on some occasions to confine the feet of prisoners, as handcuffs confine their hands.

Bille, bile (Lut. bilis, said to be derived from bis, twice, and lis, contention, as being the supposed cause of anger and dispute), is a peculiar oily fluid secreted from the blood by the liver. In man it is generally of a yellowish brown colour, and has a bitter taste. According to Berzelius, its constituents

are, in 1,000 parts, 908'4 water, 20 picromel, 3 albumen, 4'1 sods, 6'1 phosphate of lime, 3'4 common salt, and 1 phosphate of sods. The primary cells of the liver separate the bile from the blood of the portal vein, and discharge it into small ducts, which unite to orm larger ones, terminating in the ductus communis sholedochus, whence it is conveyed into the duodenum. It there mixes with the digested food, and performs the important office of fitting it for absorption into the system. The bile thus mixed with the elements of sutrition becomes in part also absorbed; the excrementatious portion passing out of the body, with the their indigestible materials, and imparting their pecuhiar colour to them. When direction is not going on, the bile ascends through the cystic duct to the galibladder, where it is stored for future use. The principal use of the bile is to separate the chyle from the chyme. It also aids in exciting the peristaltic motion of the intestines, and thus causes them to evacuate their contents sooner than they would otherwise do; for, when there is a deficiency of bile, the bowels are in general extremely torpid. When, owing to some functional derangement, the bile is absorbed into the blood and carried through the system, it imparts a ellow tint to the surface of the skin. (See JAUNDICE.) When from any cause the bile is in excess in the blood when from any cause the one is in excess in the blood, or when the liver only imperfectly performs its function of secreting it, the person is said to be bilious. (See Bitlous and Liver.)

Bilge, bilj (Ang.-Sax.), of a ship, the bottom of her floor, or the breadth of the part she rests on when aground. Bilge-water is the water which lodges on her

floor below the level of the well of the pump, and bilgepumps, or burr-pumps, are those that carry it off. A vessel is said to be bilged when her bilge is broken,

and she springs a leak.

BILIARY CALCULI (Lat. calculus, a small stone).

These are sometimes called gall-stones, and are often found in the human gall-bladder in large quantities. They are either semitransparent and crystal-line, or strongly coloured with the bile. They mostly consist of cholesterin deposited on a nucleus of phosphate of lime.

BILIARY DUCTS, bill-yū-re, in Anat., are those ducts or canals which convey the bile from the liver to the

duodemim.

Bitrous, bil'-yas, is applied to any complaint pro-ceeding from the bile. It is often indiscriminately used by patients for any derangement of the digestive organs; but though these often proceed from the bile, they do not always do so. Bilious complaints are indicated by a bitter, nauseous taste in the mouth, a foul tongue, and the appearance of the freces. The best treatment for an ordinary attack of bile is, first, to act upon the bowels by some gentle mercurial purge, a few grains of calomel or blue pill, followed in fourier five hours by a saline draught, so as to freely move Tonics should afterwards be resorted to till the digestive organs have recovered their tone. term bilious is also applied to certain kinds of food which have a tendency to produce bilious affections.

BILIOUS FEVER. (See FEVER.)
BILIOUS TEMPERAMENT. (See TEMPERAMENT.)
BILI, bill (Ang. Sax. bill, a beak), in Orn., the beak or hard horny mouth of a bird, consisting of two mandibles. There is no appearance of lips either in the upper or lower jaw; and, except in the cases of parrots in the fostal state, and some varieties of waterfowl, they are not furnished with proper feeth. In the two exceptions mentioned, the rudiments of teeth have been observed. A portion of the bill at the base of the upper mandible is covered with a membrane, which is called the cere, from the waxy appearance which it presents in some species of birds. It is sometimes covered with feathers, and sometimes it is naked; but it is often found protected by hairs or bristles. The nostrils of a bird are usually situated in the care, but in some cases they are placed so far forward as hardly to be observable. The bills of birds vary in shape according to their habits and the different substances upon which they feed. The bills of birds of prey are very atrong, the upper part being hooked, and very sharp,

dication of courage in a bird, and a sign that it prevaupon living animals. The great variety in the modification of the forms of bills is very interesting, and is treated of under the names of the different epecies of birds; such as crop-bills, spoon-bills, horn-bills, parrets, &c. In the case of those birds which live upon insects, &c. In the case of those birds which are upon the bill is very seldom found hooked, but usually short and slender. The bills of those birds which catch insects and slender. The bills for their deep division, which enables them to gape widely. Birds which live upon seeds have short but powerful bills, with which they can crush their food. Aquatic birds have, as a general rule, broad sensitive bills, which are provided with laming on the inner edge, for the purpose of straining the muddy water, from which they take the principal part of their food. The bills of every species of bird which extracts its food from mud, are modified according to the nature of the food it seeks. Besides the general use of tearing or crushing food, the bills of birds are used when fighting with each other, and slo for the purpose of dressing their plumage, building their nests, and for other functions. Many fishes and reptiles have mouths resembling bills, and the Ornithorhynchus paradoxus is a singular specimen of a quadruped with a bill.

Bill, a kind of hatchet, made in various forms, and used by plumbers, basket-makers, gardeners, and others. When short, it is called a hand-bill; when long, a hedge-bill. The bill is so called from its hooked point, which resembles the beak of a bird. It was formerly used in warfare by the infantry, as a kind of battle-axe. The billmen were principally employed in dispatching the wounded when the enemy

was routed.

BILL (from Lat. bulla, a seal), a term originally applied to any scaled letter or document, but now used to denote any formal written statement of any kind. (See the articles which follow for the particular tech-

nical uses of the word BILL.)

BILL, in criminal cases, is an indictment or written accusation of one or more persons, of a crime or misdemeanour preferred to or presented upon oath by a grand jury. When this jury have heard the evidence, if they think it an accusation groundless, or not suffi-ciently supported by the witnesses called before them. they used formerly to indoze on the back of the bill or indictment Ignoramus, or we know nothing of it; intimating that though the facts might possibly be true, that truth did not appear to them; but now they assert in English, more absolutely, "not a true bill," or (which is the better way) "not found;" and then the bill is said to be thrown out, and the party is discharged without further answer (and, by the 8 & 9 Vict. c. 114, without fees); but a fresh bill may afterwards be preferred to a subsequent grand jury, but not at the same assizes or sessions, for the same offence. If they are satisfied of the truth of the accusation, they then indorse upon it, "a true bill" (anciently they then indorse upon it, "a true bill" (anciently billa rera). The indictment is then said to be found, and the party stands indicted. To find a bill, there must, at least, twelve of the jury agree. The indictment, when so found (or not found, as the case may be), is then returned, or publicly delivered into couri, and the finding of the jury openly proclaimed, and the accused person is called un to along the least to the land of th accused person is called up to plead to it. If he plead guilty, sentence is at once passed; but if he plead not guilty, the case is tried by the petit jury; and if they acquit him, he is discharged, but otherwise he receives the sentence of the court

BILL IN CHANCERY was formerly the first commencement of a sait in the court of Chancery, which is analogous to an action in the common-law courts. There are now two other modes of instituting a suit in chancery, viz., by claim and summons, according to the matters brought before the court. The bill is in the style of a petition to the lord chancellor. This is in the nature of a declaration at common law, or a libel and allegation in the spiritual courts, setting forth the circumstances of the case at length, as some fraud, trust, or hardship, and praying relief; and if the object which they feed. The bills of birds of prey are very of the bill be to stay waste or other injury, an injunction, the upper part being hooked, and very sharp, then the same to be able to tear and cut to pieces the flesh of the animals upon which they seize. A strong short others which are merely ancillary to an action at hw, bill, with the edges sharp and notched, is the usual in-

but only evidence to be used in a court of common law but only evidence to be used in a court of common haw in support or defence of an action brought or to be brought. These are called bills for discovery. If such a bill be filed by the defendant in the action, it further prays an injunction to stay proceedings at law in the mean time. As, however, the common-lew courts have now the power to order parties to be examined on in-terrogatories, and to stay proceedings in the mean time, a bill for discovery is not resorted to except in some very appeal cases.

some very special cases.
BILL IN PARLIAMENT.

BILL IN PARLIAMENT. (See STATUTE.)
BILL OF ADVENTURE. (See ADVENTURE, BILL OF.)
BILL OF ATTAINDER is an act of parliament to
attaint particular persons of treason or felony; but,
although in former times such a process may have been resorted to, our present laws would scarcely permit such an innovation. It was also in the nature of a writ after judgment against a jury of twelve men that had given false judgment in any court of record. But the practice of setting aside verdicts upon motion, and granting new trials, has so superseded the use of it, that there is hardly any instance of an attaint for this cause later than the 16th century.

BILL OF COSTS. (See COSTS.)

BILL OF EXCEPTIONS.—If a judge of a superior court of common law, either in his directions or decisions, misstates the law by ignorance, inadvertence, or design, the counsel on either side may require him publicly to seal a bill of exceptions, stating the point wherein he is supposed to err; and this he is obliged to seal by the Statute of Westminster the 2nd (13 Edw. 1. c. 31), or if he refuse so to do, the party may have a compulsory writ against him commanding him to seal it, if the fact alleged be troly stated; and if he return that the fact is untruly stated, when the case is other-wise, an action will be against him for making a false This bill of exceptions is in the nature of an appeal, examinable, not in the court out of which the record issues for the trial at nisi prius, but in the next immediate superior court, upon a writ of error, after judgment given in the court below. Bills of exceptions are not at present so much in use as formerly, since the more frequent extension of the discretionary powers of the court in granting a new trial, which is now very commonly had for the misdirection of the judge at nisi prius.

BILL OF EXCHANGE is a security originally invented among merchants in different countries for the more easy remittance of money from one to the other, and has since spread itself into almost all pecuniary transactions. It may be defined as "an open letter of request from one man to another, desiring him to pay a sum named therein to himself, or to a third person on his account;" and by this method, a man at the most distant part of the world may have money remitted most distant part of the world may have money remitted to him from any trading country. If A. lives in Jamaica, and owes B., who lives in England, £1,000, and C. be going from England to Jamaica, he may pay B. the £1,000, and take a bill of exchange drawn by B. in Hagland upon A. in Jamaica, and receive it when he comes thither. Thus does B. receive his debt, at any distance of place, by transferring it to C., who carries over the money in paper credit, without danger of nobbery or loss. In common speech, such a bill is frequently called a draft; but a bill of exchange is the more legal, as well as mercantile, expression. These bills are either foreign or inland,—foreign, when drawn by a person residing abroad, or in Scotland or Ireland, upon his correspondent in England, or vice versa; and inland, when both the drawer and drawee reside in England. If a bill be made payable (as is most usually the case) to order, that is, either to A. B., or his order, or merely to the order of A. B. (which is in all respects equivalent), it is said to be negotiable, a term applied, in law, to any instrument, the right of action on which is, by exception from the common rule, freely assignable from man to man; and the payee may, by indorsement, or writing his name in dorse, or on the back; sasign over his interest in the bill. Such indorse-ment may either be in blank or in full. In the former case, the payee simply writes his own name; in the latter, he also defines the intended assigner, as the person to receive payment, and to him, in either case, he delivers over or sends the instrument so indorsed; and such assignee (or indorses, as he is called) may in-

dorse in like manner to another; and so on, in infinitum. If the bill be payable (as it may be) simply to a person named, and not to order, it is not negotiable; and, on the other hand, if made payable to bearer (as is always the case in that species called a cheque on a banker), it is negotiable without any indorsement, and by mere delivery; and the case is the same where a bill, payable to order, is indersed in blank by the payee; for it may afterwards be transferred, either by a new init may afterwards be transferred, either by a new in-dorsement and delivery, or by simply delivering it to the intended transferee. A bill of exchange is due (or at maturity) on the third duy of grace after the time expressed for payment on the face of it, unless it be drawn payable on demand. If the third day of grace following Seader Christope day Good Friday fall upon a Sunday, Christmas-day, Good Friday, or a day of public fast or thanksgiving, it becomes due the day before. At any time before it becomes due, the holder may present it to the drawer for his accept-ance, which must, in case of an inland bill, be by writing on the instrument; but, in case of a foreign one, it may be either written or verbal. After acceptance, if the bill be not paid on arriving at ma-turity, the holder has a right of action against any or either of the parties whose names appear thereon of the parties whose names appear thereon antecedently to his; but such right is subject to the condition that he shall have presented it to the drawee on the day it became due, and that he give reasonable notice of its dishonour or non-payment; that is, under ordinary circumstances, notice on the following day, or, to persons not residing in the same town, by the post of that day, or in case of a foreign bill, by the next ordinary post or conveyance, to all the parties whom he intends to charge, or at least to him whose name was last placed on the bill, in order that the latter may give the like notice to the party next before him; and so in succession, each party being allowed in turn a similar time for the purpose. The original payee can only resort to the drawer. If the drawee refuse acceptance,-a refusal which the law will imply, unless he accepts immediately on presentment, or within twentyfour hours after the bill is left with him for the purpose, -the drawer and indorsers are liable to make immediate payment, though the bill has not arrived at maturity; but notice of the non-acceptance must be given, as before stated in reference to the case of nonpayment. After this notice, the holder may hold it, and present it for payment when it comes to maturity, without waiving his right of recourse against the other parties. The bill need not, however, be presented for acceptance, unless it be drawn payable at a specified time after sight or after demand. Where the ceremony of presentment for acceptance is (except in the cases last mentioned) outsted, the bill must be presented for payment; and the same law of proceeding against the drawer and indorsers will then apply, as already stated in reference to the case where an accepted bill is presented for payment. The most common form of a bill of exchange is for the drawer to address it to the intended payer or accepter, who accepts it at once. It then becomes subject to all the incidents above mentioned in the case of an accepted bill. (For the law as to protest, and acceptance supra protest, for honour of the drawer, or any indorser, and other mat-ters connected with bills of exchange, consult the following writers on this subject: — Chitty, Bayley, Bylea.)

BILL OF HEALTH is a certificate or instrument granted by a consul, or other competent authority, to the master of a ship at the time of her clearing out from any port or place suspected of being liable to in-fections disorders, declaring the state of health in the place at that time. A clean bill imports that at the time the ship sailed, no infectious disorder was known to exist; a suspected, or touched bill, denotes that there were rumours of an infectious disorder, but that it had not yet actually appeared; a foul bill, or the absence of clean bills, imports that the place was infected when the vessel sailed. If the ship brings a clean bill of health, the passengers and goods are not subject to any quarantine; but, if a foul or suspected bill, they are subject to quarantines of different duration, according as the plague is known or only suspected to have existed in the country at the ship's departure. (See QUARANTINE.)-Ref. McCulloch's Commercial Dictionary.

#### Bill of Indemnity

Bill-Chamber

BILL (or Acr) OF INDEMNITY.—These are acts of parliament conscionally passed to indemnify persons who have, through forgethinness, inadvertence, or other causes, done or omitted to do certain acts whereby they have incurred penalties.

BILL OF INDICTMENT. (See INDICTMENT.)
BILL OF LADING is an acknowledgment signed by
the master of a ship, and given to a merchant or consigner, containing an account of the goods which the master has received on board from him, with a promise the deliver them at an intended place, on payment of freight. Each bill of lading must be treble,—one for the merchant who loads the goods, another to be sent to the energine, and the third to remain with the master of the ship. A bill of lading is only used when the goods sent are only part of the cargo; for, when a merchant-loads the whole of the vessel on his own personal account, the instrument passed between him and the master of the ship is called a charter-party (which

BILL OF RIGHTS was an important statute, the second of the first year of William & Mary, so called as being declaratory of the rights of British subjects.

It was delivered by the Lords and Commons to the prince and 'princess of Orange, February 13, 1688, before they were raised to the throne. The rights declared are as follows:—1. That the pretended power of dispensing with laws, by regal authority, without consent of parliament, is illegal. 2. That the pretonded power of dispensing with laws, or the execution of laws, by regal authority, as it had been then of late assumed and exercised, is illegal. 3. That the commission for creeting the Court of Commissioners for Recleviastical Causes, and all other commissions and courts of like nature, are illegal and pernicions. 4 That levying money for or to the use of the crown, by pretence of prerogative, without grant of parliament, for longer time or in other manner than the same is or shall be granted, is illegal. 5. That it is the right of the subject to petition the king; and all commitments and prosecutions for such petitioning are illegal.

8. That the raising or keeping a standing army within the kingdom in time of peace, unless it be with consent of parliament, is against law. 7. That the subjects which are Protestants may have arms for their defence suitable to their conditions, and as allowed by law. 8. That elections of members of parliament ought to be free. 9. That the freedom of speech, and debates or proceedings in parliament, ought not to be impeached or questioned. 10. That excessive bail ought not to be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted. 11. That jurors ought to be duly impanelled and returned; and jurors which to be duly impanelled and returned; and jurors which pass upon men in trials for high treason ought to be freeholders. (This provision respecting the qualification of jurors in cases of treason is repealed by the Jury Act, 6 Geo. IV. o. 50.) 12. That all grants and promises of fines and forfeitures of particular persons before conviction are illegal and void. 13. And that, for redress of all grievances, and for the amending, strengthening and processing of the level realizable. strengthening, and preserving of the laws, parliaments ought to be held frequently. It concludes in these remarkable words:—"And they do claim, demand, remarkable words:— And they do chain, demand, and insist upon all and singular the premises, as their undoubted rights and liberties." And the act of parliament itself recognizes all and singular the rights and liberties asserted and claimed in the said declaration, to be the "true, ancient, and indubitable rights of the people of this kingdom." These liberties were of the people of this kingdom." These liberties were again asserted at the commencement of the 18th century, in the Act of Settlement, 12 & 13 Will. III. c. 2, whereby the crown was limited to her present majesty's illustrious house : and some new provisions were added. at the same fortunate era, for better securing our religion, laws, and liberties, which the statute declares to be the "birthright of the people of England, according to the ancient doctrine of the common law." Some of these new provisions have been since repealed. The principal which are now in force may be shortly stated thus:—The possessor of the crown shall join in communion with the Church of England, as by law established, and, if not a nasive of England, this nation

judges shall not be removed whilst they properly & mean themselves, except upon the address of both houses of perliament, and their scharles shall be seen teined and established (and by 1 Geo. III., o. 25, 35). commissions are continued, notwithstanding the de-miss of the crown); that no pardon under the great seal shall be pleadable to an impeachment by the Commons in parliament.

BILL OF SALE is a deed under seal, which passes the right and property in chattels from one to another; and, being under seal, and therefore a solemn contract, the seller cannot, as he might in the case of a mere parol contract, show that it was made without good or valuable consideration, and that, therefore, in law, the preperty did not pass, and no action can be maintained to recover it. By the statute 13 Eliz. c. 5, every great or gift of chattels (as well as lands) with intent to defraud guit of chattels (as well as lands) with intent to defraud oreditors or others, shall be void as against the persons to whom such frand would be prejudicisl, and all persons partakers in, or privy to, such frandulent grants, shall forfeit the whole value of the goods, one moistly to the queen, and the other to the party aggreered, and also, on conviction, shall suffer imprisonment for half a year. The retaining possession by the original own year. The retaining possession by the original owner contrary to the purport of his assignment, is one of the principal badges of fraud, entitling the creditors of the original owner to impeach the transaction. And now by the 17 & 18 Vict. c. 36, it is enacted that every ball of sale shall be deemed fraudulent and void as agcreditors, where the person executing the deed remains creditors, where the person executing the deed remains in possession of the property, unless the bill of sale, or a copy of it, and every schedule thereto, with an affidavit of its execution, in which the address and addition or occupation of the assignor, and of every witness to its execution, with the actual day of its execution, be set forth and filed in the court of Queen's Bench within twenty-one days from the time of its

BILL OF VICTUALLING. (See VICTUALLING-BILL.)
BILLARDIERA, bil-lar-di-er-a (from the French botanist Labillardière), in Bot., a gen. of plants belonging to the nat. ord. Pittosporacca. The species are elimbing shrubs, natives of Australia and Tasmania, where they are commonly known as apple-berries. They have are commonly known as apple-berries. They have simple alternate evergreen leaves, and axillary pendulous flowers. The fruits are soft berries, which, when ripe, are of a bluish colour, and have a pleasant sub-acid taste. A few species are cultivated in the conservatories of this country, for the sake of their handsome flowers.

BILLBERGIA, bil-ber'-ji-a (from the Swedish botanist Billberg), in Bot., a gen. of plants belonging to the nat. ord. Bromeliacea. The species are all natives of South America. From the roots of B. tinctoria the

of SOURI America. From the roots of the source of the purchase and sale of bills of exchange and promiseory notes. They sell bills for those drawing on foreign countries, and buy bills for those remitting to them. It is their business to know the state of the exchange, and the circumstances that are likely to elevate or depress it. The rate of exchange on bills is, as in other things, regulated by the law of supply and demand; for when there is a scarcity of bills drawn upon a certain country, their value will rise; and when there is a superabundance, it will necessarily fall. When the a superacumoance, it will necessarily isll. When the value of the exports to any country in a given period is equal to the value of the imports from the same country in the same period, the bills drawn in each country upon the other will be equal in amount, and, consequently, will be about par. Bill-brokers are distinct from bill-discounters,—those who discount bills that have some time to run before they become due. (See BROKERS.)

BILL-CHAMPER, a department of the Court of Session BILL-CHAMBER, adepartment of the Court or Session in Sectiand, in which suramary potitions and applications, and other branches of business requiring unusual dispatch, are disposed of. The last-appointed lord-ordinary officiates in the Bill-Chamber during session, and all the judges, with the exception of the lord-president and lord-justice elerk, officiate in rotation during vacation. In general, wheater ages requiring tion during vacation. In general, missass requiring the immediate interposition of judicial authority, such as suspensions of decrees or of diligence, and suspensions of suspensions of decrees or of diligence, and suspensions of decrees or of decree or of decrees or of decrees or of decree or of decrees or of decrees or of decree or of decrees or of decrees or of decree or of decrees or of decree or of dec shall not be obliged to engage in war, to defend any the immediate interposition of judicial authority, such dominions which do not belong to the crown of as suspensions of decrees or of diligence, and suspensions, without the consent of parliament; that the sions and interdicts of threatened wrongs, are pro-

cooded with, in the first instance, in the Bill-Chamber. An interim interdict, by which the proceeding com-plained of is arrested till it can be inquired into and An interim interdict, by which the proceeding complained of is arrested till it can be inquired into and disquesed by both parties, is granted on the applicant making out an explain case of injury, and becoming responsible for any injury which may be occasioned by the interdict, should it ultimately be recalled. In general, he has also to find caution for the expenses of the process. The greater number of the proceedings are associated by the judge as a matter of form, on the clarks finding that the papers presented ask the usual powers in the usual manner. If a question of law is involved in the application, the point is discussed as in an ordinary action. Matters of bankruptcy or sequestration are also adjudicated on in this department. (See Essenon, Courr or.)

Britart, bit let (Fr. billot, a block, or small log of wood).—In Arch., when any moulding, either square or circular in form, but more generally the latter, is

or circular in form, but more generally the latter, is divided into short sections, and every other piece then out away, the remaining projections, which resemble short blocks of wood, are called billets. It is peculiar to Reman architecture. When several rows of mouldings one above another are ornamented in this manner, the billets are placed interchangeably; that is to say, the hollowed spaces in one line of moulding come by the side of the projections in the moulding next to it;

Biller, bil-lai (Fr. billet, a letter), in Her., a charge resembling a brick or letter in its oblong rectangular shape. By English heralds it is considered to repre-sent a letter; and hence the derivation here given; but foreign heralds are inclined to consider it as repre-

senting a brick or tile.

BILLETING, bill-le-ting (Fr. billet, a letter), in Mil., the neans by which food and lodging are provided for soldiers when on the march, or during a temporary stay in any town in which there are no barracks for their accommodation. Prior to the passing of the Mutiny Act in 1869, private persons were compelled to receive soldiers in their dwellings without any recress at the hands of the civil authorities, as the men or their officers might demand; but after this, an equitable distribution by the authorities of the place was enjoined in all cases; and since 1745 it has only been compulsory on inn-keepers of all classes, persons keeping beer and cider-Reopers of all classes, persons keeping over an cuer-shops, and those licensed to sell wine and spirits, or let horses for hire. Remuneration for food and lodging is given at the rate of 10d, per day for each man, and 9d, for the keep of a horse. The innkeeper is bound to give the soldier the means of cleaning his arms and outrements, and to provide him with one hot meal is the course of each day. It is the duty of the officers to visit daily every house where the soldiers are quartered, to see that this is not evaded by any private arrangement with the soldier, or purposed neglect. When it is found necessary to provide accommodation for troops in a town for a short time, the officer in command communicates with the mayor of the town or chief magistrate of the district, mentioning the number of men for whom food and lodging will be required. The magistrate then distributes the men as equally as possible among the various innkeepers in the town or district, and causes letters, or billets, to be prepared, assigning a certain number to each public-house. Non-commissioned officers are generally sent on in advance, who receive these billets and distribute them to the

troops as they arrive.

BILLIARDS, bill-yards (Fr. billard, the stick or made with which the ball is struck), a game played with yory balls upon a rectangular table, usually made of absteand covered with the green cloth. The size of a billiard table varies; but it is generally about 12 feet long and 6 feet broad, and is surrounded with generally made of indis-rubber, in order to keep the balls on the table and make them rebound. Two of the ivery balls employed are white, and one red. At each porner of the table, and in the centre of each of the longer sides, is an opening provided with a pocket or heard-net; and the object of the player, in an ordinary game, is either to make a cannon—that is, to hit the other white-sid and the red with his own white all .-- or to make a hazard-namely, to place his own hall into a pocket, after striking the red or white ball,— or to play so as to thrust the red or white ball into a 268

pocket. The former is called a losing hazard, and the latter a winning hazard. The stick or one with which the balls are struck is a straight wooden rod tipped with leather, between five and six feet long, and tapering towards its smaller extremity. The balls are sometimes struck with a mace, a straight she dee stick with a broad head attached to it: the mace, however, is achdom used. except by ladies and beginners. For a long period it except by ladies and beginners. For a long period it was the only instrument used in England; but gradually it was superseded by the cue, which is played over the left hand, on a "bridge" made by the fingers and thumb. The lesthern point of the cue is usually chalked before playing, in order to prevent its slipping. Before commencing to play, a fine chalk-line is drawn across the lower end of the table, nearly two feet distant from it. From the centre of this line, a semicircle is drawn, about one foot and a half in diameter, with the convex side towards the lower end of the table. The space included between the line and the semicircle is called the baulk, from which the first player always begus. In the centre of the table, at the high end, about a foot from the enshion, is a mark, upon which the red bull is placed. The game, which upon which the red ball is placed. The game, which is generally scored by a non-player, or marker, was originally 21; but it is often played to 50, 63, 83, 100, or 1,000. It can be played by two, three, four, or more persons, and there are many varieties of the game. According to Heyle, the different games played upon a billiard-table are as follows:—The White Winning game, which is played with two white balls, and is scored independently of forfeitures, from winning hazards only 12 scores the game when two persons are playing, and 15 when four play. The White Losing game, which is the reverse of the former, is scored from losing and double, or winning and losing hazards: 12 is the score in this also. The White Winning and 12 is the score in this also. The White Winning and Losing game is a combination of the two preceding : all balls put in by striking the adversary's ball first reckon towards the game. Choice of Balls.—In this game the player chooses his ball each time. The Bricole game.

Here the player must first make his ball strike a cushion, whence it must rebound so as to hit that of his cushiou, whence it must rebound so as to hit that of his adversary. The Bar-hole game, so called when the player is debarred from playing at one pecket or hole. One-hole is a game in which only the balls which go into one pocket are counted. Hazards, a game resembling Pool, which depends entirely on the making of hazards, a fixed sum being paid to the player for each hazard. The Doublet same is played with two balls, usually against the white winning game. No hazard is scored in it, ruless made by a rebound from the pushion. The Companying cappa where the safety. hazard is scored in it, railess made by a rebound from the cushion. The Commanding game, where the adversary fixes upon the ball which the player has to strike, is generally played by a superior player against the ordinary game. The Limited game is played by drawing a line across the table, and if the player's ball passes beyond it, he pays foreit. The Red Winning and Losing Carambole game, which is the game most commonly played, is reckoned from winning and losing hazards and caramboles or cannons. The cannons and white hazards score two. cannons. The cannons and white hazards score two, and the red hazards score three. The Winning Carambole, or Red game, is played with winning hazards and cannons only. The Losing Carambole, nearly the reverse of the winning, is played with cannons and losing or double hazards. The Russian Carambole is a variety of the same game. The Cardine or Carline game is played with five balls,—two white, one red, and another blue, and the Caroline ball, which is yellow. The red ball is placed on its usual spot, the Caroline ball in the centre of the table, and the blue ball at the lower end. centre of the table, and the blue ball at the lower end. The striking-place is at the upper end, in a line with the three balls. The yellow ball, when pocketed in the Caroline or middle pocket, scores six, the red hazard counts three, and the blue two. The game score is forty-two. The four game consists of two partners on each side at any of the ordinary games. They play is succession after every winning hazard lost. The cushion game consists in the striker playing his ball from the top of the baulk-cushion, instead of following his stroke upon the table. Fortification Billiards is a his stroke upon the table. Fortification Billiards is a complicated game, in which ten little wooden forts, made in the form of castles, and arches, with bells suspended in them are used. In the game of billiards, as generally played, one is scored for a miss, two for a

## Billon

white hasard, two for a cannon, three for a red hasard, and three for running a "coup," or going into a pocket without touching either of the other balls. One of the was pour consuming maner of the course cause. One of the white halls has a spot upon it, and is called the spot ball; the other is called the plain. The game of billiards appears to have had its origin in France or Italy, but there seems to be considerable doubt as to the country where it was first invented. It was, however, occurry where it was mere invenied. At was, nowever, introduced into this country from France, and for two centuries was played with two balls only. When the third, or red ball, was first introduced into the game from France, the sole object of the players was the red winning hazard,—the pocketing of the red ball. At the processed day winning and loaine hazards off the red hall present day winning and losing hazards off the red ball are the favourite strokes of the most scientific players in this country. In France the principal game of billiards is played upon a table which has no pockets, and the score is made entirely with cannons. The French game can be played upon ordinary English tables, and then cannons only are reckoned in the score. The rules of billiards are very exact, and are generally hung up in a frame where the game is played. The game of Pool is played upon a billiard-table, and differs entirely from the ordinary game of billiards. In Pool, winning hazards are the only strokes made; but, in order to master the game thoroughly, it requires a correct eye, a steady hand, and a cool head. Any number of persons can play at Pool. Each player receives a different-coloured ball from the marker, and plays in regular succession. Brery time a ball is put into a pocket by a winning hazard, the owner of the ball pays a fixed price to the player and loses a "life." At startuge, all players have those observed on the player and loses as "life." a fixed price to the player and loses a "lite. At shaling, all players have three chances, or "lives," and when these are gone, he retires from the game. The player or players who keep their balls longest upon the table win the game. When two players only play at this game, it is called Single Pool. Billiard-tables were formerly made exclusively of wood—they are now universally made of slate; and a good billiard-table, well fitted-up, costs between £70 and £80. Amongst the best players in England of late years may be men-tioned the Earl of Eglinton, Colonel Munday, and Mr. Roberts. (Ref. for rules and directions, Hoyle's

Billon, bil'-lon (Fr.), in Numis., is a composition of precious and base metal, an alloy of copper with gold or silver, in which mixture the copper predominates. In France, billon of silver was any sort of silver below the standard of ten pennies fine, and billon of gold beneath the standard of twenty-two carats fine. Billon, or black money, was, by command of the kings of England, coined in the mints of the English dominions in France, for the use of their French subjects, and was in common use from about the 13th century. was in common use from about the 13th century, Henry VIII, caused base money to be coined, that it might circulate in France. Both Henry VIII, and Elizabeth had base money, similar to billon, coined for circulation in Ireland. In North Germany the grozehen, which corresponds nearly to the English penny, is of billon, and is not unlike an English silver fourpenny lices. piece. The advantage of its use is questionable; for though it avoids the extreme weight and bulkiness of coin formed entirely of copper, yet it is ugly, dirty, and easily counterfeited.

BILLS OF MORTALITY are accounts of the number of deaths that have taken place within a particular district in a specified time, classified according to their ages, the diseases of which they died, &c. They were first compiled in London during the great plague of 1593, and ten years afterwards they began to be returned weekly, and have been continued down to the present time. Tables of this description, when their accuracy can be depended upon, are of the utmost importance as showing the progress of a people in civilization and as showing the progress as basis for many important cal-culations. The Northampton and the Carlisle tables have long served as the chief basis on which annuities, life assurances, and other calculations relating to the life assurances, and other calculations relating to the duration of human life, have been founded. By 6 & 7 Will. IV. c. 86, provision was made for a complete system of registration of births, deaths, and marriages throughout England and Wales; and the same was extended to Scotland by 17 & 18 Vict. c. 80, (See REGISTRATION.)

# Biography

the first order of Mammalia, reckoning in its numb the human species only. The term has reference than in an animal sense alone, and alludes to the tw hands which form the terminations of the fore limit arms. No other animal except man possesses too hands. The monkey tribes are distinguished by havin thumbs at each of the four extremities of their limits and are consequently called quadrumona, or four hands animals. Man, as an intellectual being, is considered so far above the brute creation, that the term bissens is not inserted in many zoological systems; but as the name only relates to the bodily structure of the human

being, it is very generally used by zoologists.

BINARY ARITHMETIC, bi-na-re, a kind of notation in which only unity, or l and 0, is used. It was the invention of Leibnitz, who proves it to be an expeditions method of discovering the properties of numbers and of constructing tables. M. Dangecourt, in the History of the Royal Academy of Sciences, gives a specimen of its operation in arithmetical progressionals, in which he shows that, as in binary arithmetic only two characters are used, the laws of progression may be more easily discovered by it than by common arithmetic. In binary arithmetic, all the characters used are 0 and 1, and the cipher multiplies everything used are 0 and 1, and the choice matthines everything by two, as in the ordinary arithmetic is done by 10. Thus, 1 is 1; 10, 2; 11, 3; 100, 4; 101, 5; 110, 6; 111, 7; 1,000, 8; 1,001, 9; 1,010, 10. It is remarkable that this system is identical with that, used 4,000 years ago by the Chinese, and left as an enigma by Fo-Hi, the founder of their empire.

(See CHEMICAL NOMEN-BINARY COMPOUND. ATURE.)

BINARY MEASURE, in Mus., is a measure which is heaten equally, or where the time of rising is equal to that of falling. It is usually called common time.

BINARY NUMBER is that which is composed of two

BINARY THEORY, in Chem. (See SALTS.)

RINDWRED. (See CONVOLVULUS.)
BINNACLE, bin'-nd-kl, in Mar., a wooden case used on board ship to hold the compasses, log-glasses, watch-glasses, and lights, to show the compass at night. On board a man-of-war there are always two binnacles,one for the use of the man who steers the vessel, and another for the officer or sailor who superintends the

SHONIAL, bi-nō-mi-āl, in Alg., an expression consisting of two members, connected by the sign + or -. Thus, a+b and 8-3 are binomials, consisting of the sum and difference of these quantities. The powers of any binomial are found by a continual multiplication of it by itself. For example, the cube, to be  $a^3+3a^2b+3ab^2+b^2$ ; and if the powers of a-b are acquired they will be found the same as the pregending. to be  $a^2+3a^2+5a^3+5a^2+5a^2$  required, they will be found the same as the preceding, only the terms in which the exponent of  $\delta$  is an odd number will be found negative. Thus, the cube of a-b will be found to be  $a^3-3a^2b+3ab^2-\delta^3$ ; where the second and fourth terms are negative, the exponent of b being an odd number in these terms. In general,

being an odd number in these terms. In general, the terms of any power of a-b are positive and negative by turns. (See ALGEBEA.)

BIOGRAPHY, bi-og'-rd-fe (Gr. bios, life, and graphe, a writing), the history of a life, the name given to that department of literature which treats of the lives of individuals. Biography differs from history in that the former is confined to an account of the actions and fortunes of individuals, while history deals with large communities of men, states, or nations. History may, indeed, be said to be the essence of innumerable biographics. Some of the earliest records that we possess are works of biography, or of biography and history combined. In the historical books of the Old Testament we meet with numerous lives of individuals; as ment we meet with numerous lives of individuals; as Abraham, Joseph, David, &c. Of purely biographical works, the most valuable that has come down to us from the Greeks, is the "Parallel Lives" of Plutarch, a work of the 2nd century after Christ; "The Lives of the Philosophers," by Diogenes Laertius; "The Lives of Philosophers," by Runapius; and "The Lives of the Sophists," by Philostratus, are the other principal works of this class in the Greek language. Of single lives, we have a life of Homer, atributed to Herodotus; of Plato, by Olympiodorus of Alexandria; BIMANA, bi-moil-no (Lat. bis, twice, manus, a hand), rodotus; of Plato, by Olympiodorus of Alexandria;

and of Apollonius of Tyana, by Philostratus. The principal hiographical works of the Romans are, "The Lives of Eminant Greek and Reman Commanders," by Cornelius Nepos; and "The Lives of the Twelve Cornelius Nepos; and "The Lives of the Twelve Cornelius Nepos; and "The Lives of the Twelve Consess" by Suctonius; the latter being necessarily in some degree historical. Tacitus has also written an admirable life of his father-in-law Agricola. Of modern biographical works the name is legion. Among the more prominent may be mentioned Vasari's "Lives of the Painters." (1850); Tillemont's "Mémoires pour servir à l'Histoire Ecolésiastique des six premiers Siècles de l'Egias," 16 vols. 4to (Paris, 1893, &c.); Stanley's "History of Philosophy," containing the lives, opisione, actions, and discourses of the philosophymical devery sect., 4 vols. (London, 1855-62); Baylo's plans of every sect., 4 vols. (London, 1855-62); Baylo's \*\*\*District of the property of Figs. (1856-7); and the Biographical section of this Diotionary. Of single lives, Boswell's "Life of Johnson" is regarded as the best in our language. In subject of subject of study. Account for it as we may, there is to man something amazingly bewitching in human nature. He has a far more intense and restless suriosity in regard to this than to any other subject of study. Every one finds in a biography something that be can understand and sympathize with; for after all, one man is pretty much the same as another. One may have a little more of this faculty and a little less of that, more reason and less imagination, higher intel-lectual and lower moral faculties than another; but, after all, there is much in common between them, the variety being sufficient to afford every one matter for comparison, it may be to feed his self-love, or it may be to strengthen and encourage him in his onway do to strengthen and encourage him in his on-ward course. "Samuel Johnson, or perhaps another," says Thomas Carlyle, "used to say there was no man on the streets whose biography he would not like to be acquainted with. No rudest mortal walking there who has not seen and known experimentally something which, could be tell it, the wisest would hear willingly from him. . . How inexpressibly comfortable to know our fellow-creature; to see into him, understand his goings forth, decipher the whole heart of his mystery; may, not only to see into him, but even to see out of kira, to view the world altogether as he views it; so him, to view the world altogether as no views it, so that we can theoretically construe him, and almost practically personate him." "Biographics," says Lord Jeffrey, "are naturally of three kinds, and please or instruct us in at least as many different ways. One sort seeks to interest us by an account of what the individual in question actually did or suffered in his own person; another by an account of what he saw done or suffered by others; and a third by an account of what he himself thought, judged, or imagined—for these too, we apprehend, are acts of a rational being, and acts frequently quite as memorable and as fruitful of consequences as any others he can either witness or perform. Different readers will put a different value on each of these sorts of biography; but, at all events, they will be in no danger of confounding them. The character and position of the individual will generally settle with sufficient precision to which class his me moirs should be referred; and no man of common sense will expect to meet in one with the kind of interest which properly belongs to snother. To complain that the life of a warrior is but barren in literary specula-tion; or that of a man of letters in surprising personal adventures, is about as reasonable as it would be to complain that a song is not a sermon, or that there is but little pathos in a treatise on geometry." In the first class he in-dudes, in its higher department, "the lives of leaders in and momentous transactions,—men who, by their force of character or the advantage of their position, have been enabled to leave their mark on the age and country to which they belonged;" and, in a lower and more private department, "the lives of individuals whom the ardour of their temperament or the caprices of fortine have involved in strange adventures, or con-ducted through the second class is chiefly for the cated serils. The second class is chiefly for the compilers of diaries and journals,—autobiographers

who, without having themselves done sayshing me-morable, have yet had the good luck to five through long and interesting periods, and who, in chronicing the events of their own unimportant lives, have indi-dentally preserved memorials of contemporary manners and events." "The last class is for philosophers and men of genius and speculation,—men, in short, who were, or such to have here, arthors, and where the were, or ought to have been, authors, and who graphies are truly to be regarded either as supp to the works they have given to the world, or substi-tutes for those which they might have given. These are histories, not of men, but of minds, and their value must, of course, depend on the reach and capacity of the mind they serve to develop, and in the relati magnitude of their contributions to its histor."

BIOLOGY, bi-ol'-o-je (Gr. bios, life, and logos, discourse), is the science of life. In its widest see it includes life in all its forms on earth, and thue com-prehends within its sphere all living organized beings. In a more restricted sense, it regards man only, and in this view it may be said to correspond with Physiology.

(See PHYSIOLOGY.)

(See PHYSIOLOGY.)
BIOTHANATUS, or BIATHANATUS, bi-o-think-d this
(Gr. bias, lite, or bia, violence, and thanatos, death), in
Med., denotes one who dies a violent death, or very
suddenly, as if there were no space between health and
death. The term was also applied by way of reproach
to the Christians in the early ages of the Church, on account of their enduring even unto the death; and were thus looked upon as little better than self-mur-

BIPAPILLABIA, bi-pep-pil-lair'-i-d (Lat. bis, twice, papilla, a nipple), a term applied by La Marck to a gen.
of marine Mollusca, described and illustrated by Peron in his manuscript notes. La Marck defines it as pos-sessing a naked body, of a shape between oval and globular, terminated posteriorly by a tail, having at its extremity two conical papills,—whence the name.

BIPED, bi'-ped (Lut. bis, twice, and pes, pedis, a foot), an animal having two feet; as man, bird.

BIFES, bi'-pess (Lat. bis, twice, pes, a foot), a gen. of reptiles belonging to the ord. Saura, or Lizards. It is interesting as showing the gradation between one type of animal form and another, and is the connecting link between the Lizard and the is the connecting link between the Lizard and the Serpent. One of the species, the Bipes lepidopodus of Lacépède, was dissected by Cuvier, who found that though its posterior and only apparent pair of feet had merely the external form of two scaly plates, the integument, in reality, covered a femur or thigh-bone, a tibia and fibuls, lep-bones, and four metatarsal or finger-bones. He, however, found no phalanges or terminal finger-bones; and also noticed that one lung was larger than the other by one half. The Bipes lepidopodus of Lacépède has the body and tail very alender and almost cylindrical, and bears a resemblance slender and almost cylindrical, and bears a resemblance to the common blind-worm or slow-worm (Anguis fragilis), so common in many parts of England. These to the common blind-worm or slow-worm (Angust Pragilis), so common in many parts of England. These reptiles also possess the rudiments of limbs in their sheletons. The Bipes lepidopedus has the upper part of its head protected by nino large scale-plates; its eyes being surrounded with small scaly globules. Its teeth are equal and small, its mouth large, and its tongue, which is long and flat, is not notched. The organs of hearing are situated above the angle of the lips. The scales on the under-part of the belly and tail are hexagonal and smooth, but the scales on the back are lozenor-shaped, strigted and small carrecitles. back are lozenge-shaped, striated, and small, especially those in the highest part. About the centre of the reptile, two rudimentary feet, with no appearance of fingers, and covered with small scales, can be observed. Its colour is greenish, with small black blotches seat-tered over it. It is a native of Australia. Lacopade says of it, "This reptile, like the other species of bipes, ranks between the oviparous quadrupeds and the serpents. It is related to the latter by its general form as well as by the figure, proportion, and distribution of

as well as by the figure, proportion, and distribution or the scales, while it approaches the former by its auditory spertures, and by the hollow tubercles near the enus." BITUTILLATE, bi-pu'-pil-laif (Lat. bis, twice, pu-pila, a pupil), in Bnt., a term applied to that apot upon the wing of a butterfly resembling an sys, and having two dots or pupils of different tints within it. BIQUADRATIC FOWER, bi-quod-rai-life (Lat. bic, twice, and quadratus, squared), in Alg., the fourth

power or aquared square of a number or quantity; as 16 is the biquadratin power of 2; for 3×2 is 4, and 4×4 is equal to 16.—Biquabaara Boor or a Number is the square root of its square root; thus the biquadratic root of 61 is 3; for the square root of 81 is 9, and the square root of 9 is 3.—Biquabaara Equation, an equation where the unknown quantity of one of the terms has four dimensions. Any biquadratic equation may be generated by the multiplication of four simple equations; or by that of two quadratic canualtons. quadratic equations.

BIRCH. (See BETULL.) BIRCH. (See HETTLA.)
BIRD-BOLT, bird'-belt, an old form of arrow, to
which Shakepere, in "Much Ado about Nothing,"
thus alludes: "And my uncle's fool, reading the challenge, subscribed for Cupid, and challenged him at the
bird-bolt." Stevens, in a note upon "Much Ado about
Nothing," explains that the bird-bolt was "a short, thick arrow, without point, spreading at the extremity so much as to leave a broad flat surface, about the breadth of a shilling. Such are to this day in use to

kill rooks with, and are shot from a cross-bow. BIED-CATCHING, the art of taking birds or wild wi alive. It is performed in a variety of ways, ac-BIRD-OATCHING, the set of taking birds or what fowl alive. It is performed in a variety of ways, according to the season of the year or the species of bird intended to be caught. Some birds are taken by burning sulphur at night under the trees upon which they have been observed to perch. Pheasants are sensitimes caught in this way. If wheat or any other grain, steeped in a mixture of wine-lees and hemlocking, be scattered in places where birds resort, they become intoxicated after eating, and are easily taken.

Birds are also taken

Birds are also taken

by means of birdlime (which sce). The principal methods employed in catch-

ing birds, however, are by

traps and nets. Like everything else, the

trapping and catch-ing of birds is a

trap is the common brick-trap, repre-sented in the illus-tration. It consists of two bricks placed lengthwise upon their narrow sides, a third across their extremities, and a fourth at the opposite end, so as to form a sort of lid. In the central opening a stout piece of

stick is driven, and

means of

BRICK-TRAS

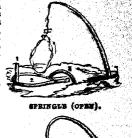

SIEVE-TRAP.

between this and shother similar piece supporting the lid, a forked twig is placed. When the bird alights on one of the forks is placed. When the bird alights on one of the forks of the twig, the other two sticks give way, and the lid falls, securing the bird. The next essiest of construction is the sieve-trap, shown in the accompanying woodcut. An ordinary siove in the accompanying woodcut. An ordinary siove is propped up by a slight stick at an angle of about 45 degrees: some seeds or crumbs of bread are strewn under the sieve, and a string attached to the supporting stick is held by the birdeatcher, who remains concealed at a short distance. When the birds gather round the food, the string is pulled, the sieve falls, and the birds are caught. Tho mext bird-eatching machine, the springle, is more diffi-cult to construct. At the smaller end of a hazel switch Sur feet long, which is called the spring, a piece of string about fifteen inches long is tied. Nearly at the end of this string, the catch, which is a little piece of wood half an inch long, about half as broad, and one

#### Bird-oatching

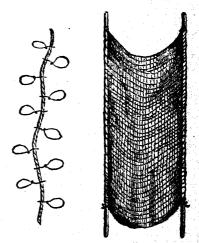

featened to the end of the string below the eatch, smaller switch, about a foct and a half in length, hent back at the smaller end, and featened within inch or so of the thicker end, in which a notch is o in order to receive the end of the catch; this is cal

the spread. A stump and a bender, which is another pliant bit of switch, each a foot and a half in length, complete the sprin-gle. It is set in the following manner :-The stump, No. 1 in the engraving, is thrust into the ground; the bow of what is called the spreader is placed over it, as No. 2; and then, about the length of the spreader from the stump, the two ends of the bender are pushed securely into the ground, as No. 3. The thick end of the long switch or spring is then planted at a convenient distance from the bender. It is bent down until

one end of the SPRINGLE (SET).

catch can be put upward on the inside of the bender. After lifting the spreader an inch from the ground, the smaller end of the springer is the catch is placed in the notch, and the springer is retained from springing up. The hair slip-knot is lastly laid round the spreader, and some crumbs or seeds laid in the inside of the trap and scattered about its neighbourhood. The springic is then set, and appears as in the illustration. When the bird alights trapping ing of birds is matter of practice, study, and expense. The most form of Ms heighnourhood. The springle is there were appears as in the illustration. When the bird slights upon the spreader, it falls with its weight, the catch is released, the springer flies up, and the bird iscaught by the neck, wings, body, or legs, in the horsehair alip-knot. A number of birds are caught by horsehair

HORSE-HAIR LOOP.

loops which are fastened to a long string, which is laid in a series of rings winding outward from the centre, wood haif an inch long, about haif as broad, and one in a series of rings winding outward from the centre, country as thick, is fastened. A small piece of the wood as that the space of ground is covered with them, is aboved off one side of this catch, in order to adapt. When disposed in a place warp birds resort, it is for a notch in another part of the springle; a loose generally occurs that if a bird gets his continuous alip-knot made of two long stout horsehairs is then the draws it tightly round his log, and is thus caught.

# Bird-natching Spider

Another mode of catching birds is by what is called "bat-fowling" and "bush-beating." The methods described above are employed by daylight, and with the assistance of decoy-birds, which, trained for the purpose, are placed in cages, about six or eight yards apart, and covered with branches to hide them. Their call-note allures the wild birds. Bat-fowling is pursued at night-time, some two or three hours after the birds have gone to roost. A large net, of the shape shown in the engraving, is mounted on two long poles. the birds have gone to roost. A large net, of the shape shown in the engraving, is mounted on two long poles, which are carried by two persons. Some of those engaged in the sport walk in front of the net, beating the tunbes, ivy, &c. Others walk behind the net, carrying a dim light in a bull's-eye lantern. The birds being disturbed, if yout naturally towards the light, and, in so doing, ity against the net, which is quickly doubled ever, and they are caught. Vaillant, in his "Travels in Africa," states that, in order to take certain birds alive, be put into his fowling-piece, above the powder, the end of a candle, ramming it well down. He then filled the barrel with water, with which he fired at the birds, and captured them alive and uninjured. In the Orkney Islands, eggs and young birds are collected by Orkney Islands, eggs and young birds are collected by the inhabitants in a most daring and hazardous manner, chimbing up rooky precipices, and sometimes being enspended by ropes, over the verge of clifts 300 to 400 feet high. In the Faroe Islands, still further north, the fowlers employ a similar method. The clifts are 1,200 feet high, and a rope 600 feet long is tied round the writer of the market in large of the root of t the waist of one man, who is lowered down the precipice by six associates. A piece of board is laid upon the margin of the rock to prevent the rope from being cut by the friction. In Mexico and China, empty gourds are left continually floating in the inland lakes where aquatic birds resort. The bird-catcher enters the lake with his body under water, and his head covered with a gourd. He quietly approaches the birds as they are swimming, and pulls them under water. In many parts of Russia, the gellinotte, or grouse, is taken in large quantities by means of an ingenious trap, made of birch twigs in a conical shape, with a movable wheel at the top. In Italy, the wild pigeons, on their return from the northern and western parts of Europe, are caught by means of nets, which are stretched across the hollows of the mountains through which the birds and nollows of the mountains through which the birds direct their course. A variety of other modes of catching birds will be found described in Pennant's "Birds of Great Britain," Buffon's "Histoire des Oiseaux," and in an article entitled, "Birds: how to trap and catch them," in Beeton's Boy's Oun Magazine.

BIED-CATCHING SPIDER (Mygale auricularia), an immense black hairy spider, a native of Cayenne and Surinam. It is nearly two inches in length, and its feet when stratched out covers a surface of reaching

feet, when stretched out, cover a surface of nearly a foot in diameter. The hooks of its mandibles are conical and very strong. It does not construct a web for the capture of its prey, as do other spiders, but builds in clefts of rocks or hollows among trees, a funuel-shaped cell of a transparent tissue, resembling fine muslin, and which it itself provides. oung one musin, and which it itself provides. There it lurks till insects, or, as is reported, even small birds, approach, when the spider darts out and secures its victim. Dampier mentions a spider of this genus, found at Campsachy, the fangs of which were "black as jet, smooth as glass, and at their small end sharp as a thorn." These fangs, according to the last-mentioned authority, are worn by some persons in their tobacco-pouches to prick their pines with and to be be athered. pouches to prick their pipes with, and to be, by others, used as toothpicks, in the belief of their having the power to expel the toothache. There are several bird-catching spiders besides the one in question, and they are found in America, the East Indies, and Africa. As well they make a web like the correspondent a rule, they make a web like the common European spider, but of such tough threads, that a thrush would scarcely be able to force a passage through. It is even declared, that, in certain tropical forests where these spiders abound, their nets will often impede the progress of the traveller. The bite of the larger species of this genus is said to be dangerous to human life.

Bush Churren. (See Cransus.)

Bush Larger species of this genus is said to be dangerous to human life.

Bush Churren. (See Cransus.)

Bush Larger species of the bound of the holly, and meet for extehing attist. The bark is bruised, boiled with water till very soft, and then placed in pits to ferment. After two or three weeks, a curious viscid mass a rule, they make a web like the common European

# Bird of Paradise

is found in the place of the soft bark : this is boiled is found in the piace of the sous serial rouns is possible with a fresh quantity of water, and evaporated to a proper consistence. Birdlime may also be prepared from the berries of the mistletes, from the young shoots of the elder, and from the cellular portions of other plants. When used, it is spread on twigt or wire-netting, and the wild birds are often drawn to the sticky perches by the treacherous singing of a decoy bird, placed in a cage near to them.

bird, placed in a cage near to them.

BIRD OF PARADISE, GREATER, për'-à-dies (Paradise Major).—These natives of New Guinea may be justly regarded as the most magnificent of the feathered tribes. Concerning them the most fanciful conjectures have been indulged in, not the least curious being one encouraged by Buffon, that the bird, having no feet, and being unable to walk or swim, was compelled to live entirely on the wing. This error, doubtless, took root in the fact that the legs of the bird being its least ornamental parts, were detached from the akin root in the fact that the legs of the bird being its least ornamental parts, were detached from the skin before they were prepared for exportation. They have great diversity of beauty. Some of them have thinly barbed feathers to cover the closed wing, so prolonged as to form immense tufts, and extending far backward beyond the body. The greater bird of paradise is rather longer than the common thrush. Its general colour is a deep cinnamon, with the exception of the top of the head and the back of the neck, which is a deep yellow; the feathers which decorate the base of the breast, and cover the whole of the throat, are of a pure emerald green. In the male bird, there springs from each side of the chest a full plume, from sixteen to eighteen inches long, composed of slender shafts, with loose, delicate webs. In some specimens they are bright yellow at the base, fading gradually into straw-colour. From the tail-coverts spring two slender, naked shafts of great length, which taper gradually to a point, and are of a rich brown. The Magnificent Bird of Paradise (Magnifica) is somewhat smaller than that above-described, and is chiefly distinguished by a double sort of ruff, composed of deep yellow; the feathers which decorate the base of distinguished by a double sort of ruff, composed of slender plumes that spring from the back of the neck. More of purple and blue enter into the plumage of this bird than the former. The King Bird of Paradise (Regia) is the smallest and the most precious of the family, both on account of its rarity and its splendid colours. It is scarcely as large as a sparrow. upper parts of its body are of the richest chestnutbrown, and the under parts dazzling white. A zone of prown, and the under parts dazzung white. A zone of golden green extends across the chest; from the sides spring two fan-like plumes, consisting of six or seven dusky feathers of the richest golden green. From the tail-coverts spring two long, slender shafts, each elegantly termnasting in a broad emerald web, rising from one side only of the shaft, and disposed into a flat spiral curl. The breast and legs are yellowish-brown. These birds fly in flocks of about tharty or forty, led, it is said, by a single bird. They fly against the wind, lest their plumage should be discomposed. When flying they make a noise like starlings; but their common cry is little more melodious than that of the raven. They are captured by birdlime and blunted arrows. No pains are taken to preserve them alive: as soon as they are captured they are killed, embowelled, their feet cut off, the plumed skins impregnated with sulphur, and then dried for sale. The skin, to which a great part of the flesh is allowed to remain attached, great part of the ness is showed to remain actaonees, is always much contracted by this drying process, and a very erroneous idea is sometimes formed of the size of the bird. With respect to their food, scarcely anything certain is known. Mr. Shaw, drawing the inference from the strength of the beak and legs of some of these birds, thinks it likely that they pray on the smaller of the feathered tible. Some they prey on the smaller of the feathered tribe. Some naturalists assert that they live on fruits and berries; and Linners, that they devour the larger butterflies. Bennet, in his "Wanderings," gives an account of one of these birds he saw in Mr. Beale's aviary at Macao, of these birds he saw in Mr. Beale's aviary at macco, where it had been confined nine years, giving no appearance of growing old. It ate insects in a living state, but would not touch them dead. When an insect was thrown into its cage, it contrived to catch it with great agility. It washed itself regularly twice a day, and after having performed its ablutious, threw its delicate feathers up over its head hood-wise. Its chief food during confinement was boiled rice and egg,

with an occasional bit of plantain, and a grasshopper or other insect. The Zoological Society of London have just enriched their collection by two young males of the Losser Bird of Paradise (Paradisea papuensis), brought from New Guinea in good health and fine

condition.

BIED'S.EXE VIRW.—The representation of a building; town, or any tract of country, as if seen from a considerable height immediately above it. The method of presenting a bird's-eye view of any place, in the common acceptation of the term, is to fix the horizontal line containing the point of sight (see PRESENCTIVE) considerably above the drawing, which renders it nothing more than a common perspective which is seen under circumstances which can renders to noming more cure in a common perspective, which is seen under circumstances which can scarcely be considered natural. The view so obtained is that which would be seen by a spectator standing on the top of a very high tower or mountain, and looking directly before him. In a true bird's-eye view, a ground-plan would be represented with great exactness, with all the objects that appear in it, at their relative distance from each other. In such a drawing, no side-view of a building, or any object rising from the surface of the ground, could be obtained. A correct idea of what true hird's-eye perspective would be may be gained by placing a small model of a hollow cube, or any building with its outhouses and surrounding walls and fences, on the floor of a room or a table, and looking down upon it while standing over it. It will be seen, as the eye is above the picture and looking down upon it, that the plane of the picture is parallel to the natural horizon, instead of being perpendicular to it; but that the rules which govern the relative position of all objects shown in the picture so formed are exactly the same as those adopted in ordinary perspective, the difference being in the position of the spectator only; as, in making a drawing in true

or the spectator only; as, in making a drawing in true bird's-eye perspective, he must consider himself as being above his picture, while, in the latter case, he is supposed to be standing directly opposite to it.

BIRD'S-MOUTH, in Arch, a small angle entering into any moulding, or a notch cut in the end of a piece of timber, to allow it to fit and rest upon the edge of another piece bearing on the upper surface, and on one eide, as rafters are sometimes cut to bear on the wall-ulate.

on the wall plate.

Birns (Ang.-Sax.), feathered vertebrated and ovi-parous bipeds, which are generally so constructed as to be able to support themselves in the air, and make progress through it. Every place in nature make progress through it. Every place in nature is furnished with its proper inhabitants. Both the land and the occan are illed with living creatures, each of which is so constituted as to be especially adapted to the course of life through which it is to pass. The great realms of air have their special occu-pants—the birds, whose extreme beauty, variety, swiftness of motion, and buoyancy on the wing, are admired by all. Blegant and symmetrical as the outward form of the bird is, it is surpassed by the internal construction, which is peculiarly adapted to its habits and mode of living. The large head, broad shoulders, deep chest, of lying. The large head, proad shoulders, deep cuest, and sinewy limbs of the quadruped, are replaced in birds by the pointed beak, the long supple neck, the gently-swelling shoulder, the expansive wings, the tapering tail, and the light, bony feet, all of which assist them in their motion through the atmosphere. Their bodies are protected from the intense cold in the air by a soft and delicate plumage, and their wings, air by a soft and delicate plumage, and their wings, although made of the lightest materials, are so powerful as to be able to strike the air with great force; their tails also serve as rudders, steering them in any direction they please. Internally, the frame of a bird is quite as wonderfully and appropriately constructed. All the benes are thin and delicately formed, except the sternum, or breast-bone, which is very large and strong. The clavioles, or collar-bones, are generally joined, forming the bone called the merrythought, which, together with two bones called the coracoid bones, keep the shoulders apart, and serve to resist the compressing action of the wings. All the muscles, except the pectoral nuscle, are small and light. In men and in quadrupeds, the pectoral muscles are In men and in quadrupeds, the pectoral muscles are small when compared with those of birds, which are very strong, and are situated on either side of the breast-hones. These muscles are used for moving the

wings. The anterior extremities of birds are al wings, and never arms or legs. In the cases of bir wings, and never arms or legs. In the bases of birds whose wings are too small to enable them to fig. they are used either as paddles in the water or to assist them in running. The great suk is an instance of the former, and the extrich of the latter. The lungs of a bird are situate close to the backbone and ribs. The six entering them from the windpipe, passes through, and is conveyed to a number of membranous cells which lie upon the sides of the pericardium, and communicate with those of the sternum. These cells are in some birds continued down the wings, and even to the pinions and thighs, and other parts of the body. They can be filled with air at pleasure, and by this means the bird can render his body heavy or light, when necessary, either in flying, swimming, or running. The vertebral column in birds is usually rigid in the central parts and flexible at both extremities. By this means the ribs are strengthened, and the free motion of the neck and tail assisted. In birds which do not fly, the vertebrase retain some amount of motion throughout the back; but, in general, they become ankylosed, or firmly united and cemented together by bone. The skull differs from that of the mammalia; the cranial bones are consolidated, and there are no autures in the skull of a bird. It is articulated to that part of the vertebral column called the neck by one condyle or joint, which is situated at the front margin of the great pital opening, through which the brain descends into the vertebral column, being prolonged as it were into the spinal cord. It is by this peculiar formation that birds have so free a motion of the head and neck, especially in a horizontal direction. The wryneck is a especially in a horizontal direction. The wryners is a special instance of this faculty; and many a youthful bird-nester has been scared from a wryner's nest when he has seen her twist her head completely round, hissing all the time like a snake. Birds generally alsop with the head turned back and nestled under the wing. In mental capacity, birds fully equal quadrupeds, and in some respects, indeed, surpass them. In some of the songsters, the brain has been said to exceed that the songsters, the brain has been sau 50 exceed that of man, when considered with reference to the comparative size of the head and body. The size of the brain of an eagle in relation to its body has been reckoned to be which part, that of a canary-bird with, and that of a man words and part. Parrots and starlings retain many words and phrases fixed in their memories, and some singing-birds remember whole melodies. Birds of passage, after travelling thousands of wiles and after being absent for a great length of of miles, and after being absent for a great length of time, remember the exact spot where their nests were previously located, or where they were reared. Prodence, cunning, and docility, are practically exempli-fied in the different positions in which birds build their nests, some in the neighbourhood of human beings and some in uninhabited places. Sight, smell, and hearing, are the most acute senses in birds. There are two classes of birds,—the carnivorous and the granivorous; classes of birds,—the carmivorous and the granivorous; and there is a middle kind, as in quadrupeds, which partakes of the nature of both. The carnivorous class is provided with long wings, furnished with very powerful muscles, in order to be able to fly great distances. They have strong hooked beaks, and sharp formidable claws; they have large heads, short necks, and strong, sinewy limbs; their sight is wonderfully acute, so as to enable them to see their prey at a great height in the six and they swoon down upon their victims with the air; and they swoop down upon their victims with an unerring aim. Carnivorous birds are solitary and sullen, and seldom live together in flocks. Granivorous birds, whose food consists of grain of various sorts, have larger intestines than carnivorous birds, and their digestive organs are more complicated. The form of the bill varies, according to the kind of food which the bird subsits on. (See Bill.) The food is passed from the bill into the stomach, which consists of three parts,—the crop, which lies in front of the breast-bone, the membranous stomach, and the gizzard. In the me memoranous stomach, and the gizzard. In the crop, the food undergoes a partial dilution from a fluid furnished by the glands. In the membranous stomach it is still further diluted, and then passes into the gizzard, which acts as a powerful mill, and in which the food is ground down and tritural triangle action of the gizzard is stangethand by many label the country in the country of the gizzard is stangethand by many label the country of the gizzard is stangethand by many label the gizzard is stangethand by many labels and the gizzard is stangethand by many labels and the gizzard is stangethand by many labels and the gizzard is stangethand by the gizzard in the gizzard in the gizzard is stangethand by the gizzard in the gizza the gizzard is strengthened by small hard stones, which many birds awallow with their food. The digestive powers of the gizzard are very extraordinary. An experiment was tried upon a turkey-cock, when a ball of lead, studded with twelve-small lancets, was forced down his throat. After eight hours had passed, the gizzard was opened, and the ball was found by itself, the whole of the lancets being broken to pieces. In the London museum of the College of Surgeons than in June 2014. of the College of Surgeons there is a large bottle entirely filled with publics, &c., taken from the stomach of an In some experiments tried upon a ben, it was found that a louis d'or, after being swallowed for four days, lost sixteen grains; and the weight of an onyx was diminished one-fourth. In carnivorous birds the The liver of domestic hirds is much larger than that of wild birds. It is considered a delicacy among • wide birds. It is considered a deleacy among governmends; and paties do foic gras are made from the enlarged livers of geese. The eyes of birds are admirably adapted for sight. The impression of external objects is rendered more vivid and distinct by a particular modification of the optic nerve. They have three eyelids, two of which, the upper and lower, are closed in most species by the elevation of the lower one. This may be noticed in domestic fowls. A small number of birds such as the owl and gost-sucker, can depress the apper eyelid. The third eyelid, a thin semi-transparent membrane, lies, when at rest, in the inner corner of the eye, with its loose edge nearly vertical. It can be drawn over the eye like a curtain; and by its means the eagle is said to be able to look at the sun. Were the eyes of birds less perfectly formed, on account of the rapidity of their flight, they would be liable to fly against any object in their way. The voices of birds distinguish them from all the rest of the animal world. The organs of the voice closely resemble certain musical instruments. At the bifurcation of the windpipe is a glottis furnished with appropriate muscles, where the voice is formed. The gift of song is only possessed by male birds, and their notes are generally expressive of love. They are silent when in ill health, in sadness, or love. They are shent when in in nearth, in sadness, or during rough weather; but when they are cheerful they always sing. They express different feelings with varied modulation; and the fear of approaching danger, hunger, love, longing for their mates, &c., are all expressed by changes in the tone of the none. This faculty is possessed by no other animal. Every form which the most lively fancy could create, and every hue that the imagination could conceive, are to be found in the feathers of birds. Two changes occur is the feathers,—one in the spring and another in the samema. In the former case the change occurs just before the breeding-time, and the bird gains a number of new feathers without losing the cld ones. In the latter, or moulting season, the old feathers fall off and new ones appear. The feathers of the wings are larger and stronger than those on other parts of the body. They are called wing-feathers, quill-feathers, or quills. At the hase of each quill are small feathers called wing-coverts. The tail-feathers are also provided with coverts above and below. Many birds have vary ornamental plumage in their tails; and the feathers often take other remarkable forms in different parts of the body; such as shoulder-tuffs, ruffs, crests, &c When and in the feathers of birds. Two changes occur the body; such as shoulder-tufts, ruffs, crests, &c When spring approaches, wild birds begin to pair and to make spring approaches, their young. The notes of the male birdst this time are very loud; and the marriage contract birdsthistime are very loud; and the marriage contract then entered into is for the season faithfully adhered to. In case one of the pair dies, its mate does not survive it long. The reproduction of the species smoog birds is carried on by means of eggs, which pass from the body of the female and are afterwards hatched. The warnth necessary for incubation is usually derived from the body of the bird, which sits upon the eggs. pon the eggs. This duty is generally performed by the female bird; but in some cases it is undertaken by the male. (See Egg, HATCHING, REPRODUCTION.)
Minny sea-fowl make no nests, but deposit their eggs
on the bare rock, or in rough boles scratched out of the earth or sand. The ostrich allows her eggs to be satehed by the heat of the sun in warm climates; but the site and broods over them where the temperature s colder. Birds generally brood once in the year, but senses. Birds generally proof once in the year, but see brood twice; and the number of eggs they lay res from the price of twenty. The cuckoo and a small mber of other birds ley their eggs in the nests of ser birds, in order to be hatched by them; and small birds are able to run about and find food as 274

soon as they leave the nest, while others remain in the nest for days and weeks before they can venture out. During this period the parent birds find food for them. At the breeding-season birds are often gragazious, and sometimes live together in one large nest. Birds nests are constructed with such delicate and exquisite art and ingenuity, as to call forth the admiration of every—beever. Birds of the same species, wherever they may be found, build their nests with the same kind of materials and in the same manner. The situations they select, the materials they use, and the form in which they build, are wonderfully adapted to the particular nature and necessities of the bird. They are generally lined with moss, wool, fine hair, or down, and have an exterior composed of straws, twigs or roots, and dry grass, mixed with clay. Birds that build early in the spring, such as the blackbird and thrush, line their nests with loam, in order to keep out the cold air. The common sparrow, who builds four or five nests in the year, is not particular as to the situation he chooses. Sometimes he locates himself in ivy, sometimes in trees and hedges, and often under the eaves of houses. Some birds carefully conceal their nests, and some leave them open and apparent; some, like the jay, build them so loosely that the eggs can be seen through the twigs; and some very compactly, such as the golden-crested wren, which constructs its nest with small pieces of moss and spiders' web interweaved. It is nearly an inch in thickness, and is lined with a profesion of soft downy feathers. While hatchwith a profusion of soft downy feathers. While hatching, all birds, as a general rule, resort to those places where their particular food is plentiful, and where there is an abundance of the proper material with which to construct their nests. Some water-fowls pluck the down from their own breasts, in order to line their dwellings; but they usually build in out-of-theway places, since their food is not that which is gathered way places, since their food is not that which is gathered, by ordinary birds. While hatching, the female bird is remarkably patient. She is usually plump where she begins to sit; but before the eggs are hatched she is almost reduced to a skeleton. Neither hunger nor danger will make her leave her post of duty; but if, after being absent, the male and female birds perceive. that their nest has been meddled with, they will often leave, and build in a securer place. After the young are fledged and flown, the nest is generally deserted. Many small birds live upon worms, caterpillars, &c.; and it has been remarked, "that a single pair of sparrows, during the time they are feeding their young, sparrows, during the time they are feeding their young, will destroy about four thousand caterpillars weekly; they likewise feed their young with butterflies and other winged insects, each of which, if not destroyed in this manner, would be productive of many thousands of caterpillars." The sparrow is usually believed to of caterpiliars. The sparrow is usually believed to of caterpilars." The sparrow is usually believed to be the gardener's enemy; but this would seem to show the reverse. Whilst moulting or changing their feathers, many birds turn sickly, and often die. Every country and climate have birds which are peculiar to them; but many migrate to distant lands when the season becomes too severe for them. Near the equator the birds are remarkable for their brilliant and varied plumage; but their voices are usually harsh and discordant. In the frigid zone, where fish is plentiful, they are mostly aquatic, and their plumage consists of soft, warm, downy feathers. In all countries birds live longer, comparatively, than either men or quadrupeds in the same place. Alany kinds of birds are important in an economical sense. A large profit is derived from the rearing of domestic fowls; and the flesh and eggs of most birds can be eaten. The flesh of fish-cating birds and birds of prey is considered unpleasant. Feathers are employed in many useful and ornamental ways, and the dung of birds is useful for manure. (See GUANO.)
From the earliest periods birds have been objects
of interest. Amongst the ancient Romans and Greeks, their habits and customs were not only well known to the husbandmen and augurs, but even to the general the husbandmen and angurs, but even to the general mass of people. Several poets refer to them as the harbingers of various seasons; and the title of one of the plays of Aristophanes is "The Birds." Aristotle, in his History of Animals, describes the classes and habits of birds accurately and philosophically; and in Pliny's Natural History the subject is also treated in a very learned manner. Pierre Belon, in 1555, was the first classicity of the property and the subject in the subject is the subject to the subject in the subject in the subject in the subject is the subject to the subject in the subject in the subject in the subject in the subject is the subject to the subject in the sub first goologist of note who wrote upon the subject of

## Birdmests

birds in later times. He placed the repactors birds first, the waders second, the swimmers third, and the which build their nests in trees or on the ground birds which build their nests in trees or on the ground fourth. About forty years afterwards, Aldrovandus of Bologna produced his work called "Ornithology." He followed the same arrangement as Belon, and added many new particulars of the habits and haunts of the several birds described. Francis Wilsughby, an Enseveral birds described. Francis Willinghby, an English gentleman, was the first naturalist in modern times who reduced ornithology to a system. His "System of Craithology," edited by Ray, the celebrated Cambridge professor, is a work of great merit. In it, hirds are divided into two general classes,— "land birds" and "water birds." The former are divided into those which have crooked and those which have straight beaks and talons; the latter are di-vided into three sections,—first, the waders; secondly, those which are of "a middle nature between swim ners and waders, or, rather, that partake of both kinds, some whereof are cloven-footed and yet swim, others whole-footed, but yet very long-legged, like the waders." The third class of water-birds consisted of waders. The third class of water-birds consisted of palmated birds, or swimmers. Ray's edition of Willinghby was, again revised and edited by Dr. Derham in 1713; as upon the works of these three naturalists Linnaus formed his ornithological system; and the orders in his class Aves are as follows:

1. Accipites.—Birds of prey, properly so called.
2. Pice.—Woodpeckers, crows, humming-birds, kingfishers, &c.

3. Anseres.—Swimmers. 4. Gralle.—Waders.

5, Galling,-Gallingceous birds; such as grouse,

partridges, and domestic fowls.

6. Passeres. — Sparrows, swallows, finches, doves.

6. Fasseres. Sparrous, swanow, menes, doves, thrusbes, &c.
In the year 1760 Brisson introduced his system, in which birds were divided into two classes,—those whose toes were furnished with membranes through their entire length, and those whose toes were without membranes. Buffon published his work upon birds in 1770, and Scopoli another in 1771. Cuvier, in 1817, published a new method, dividing birds into six classes at the same time expressing an opinion that all the systems he had seen were wrong. At the present day, it is also true that a correct arrangement has not yet been made. About 5,000 species of birds are known to exist; and the Dodo is a remarkable instance of a genus of birds which has recently become extinct. Class II. of the sub-kingdom Vertebrata, will be found one of the best modern arrangements. Amongst the most celebrated writers on the natural history of most ceisbrated writers on the natural instory of birds in Britain may be numbered Pennant, Lewin, White of Selborne, Bewick, Montagu, Donovan, Selby, Mudie, Macgillivray, Thompson, Meyer, and others. In America and the West Indies the principal anthors in ornithology have been Hernandez, Marc-grave, De Azara, Sloane, Catesby, Vieillot, Wilson, grave, De Azara, Sloane, Catesby, Vicillot, Wilson, Spir, C. L. Bonaparte (prince of Canino), Audubon, Richardson, Swainson, and Nuttall; while the birds of Europe have been learnedly treated of by Temminck, Meyer, and Wolff. Gould has written several valuable works, not only upon the birds of Europe, but upon the birds of Australia, the humming-bird, the toucan, &c. Several other illustrious authors have distinguished themselves in their works upon ornithology; amongst

themselves in their works upon orthology; amongst whom may be mentioned Buffon, Cuvier, Illiger, Strickland, Syme, and Yarrell. (See Obstructions.)
BIEDSNESTS, EDIBLE, the nests of a small Indian swallow, which are considered a delicacy, and are frequently mixed among soups. On the seaconsts of China and in Java, at cortain seasons of the year, vast numbers of these birds are seen. At their breeding, the state lears the inland counter to build in the time they leave the inland country to build in the rocks. They construct their nests out of a substance which they find upon the shore. This gelatinous matter is supposed by Kempfer to be molluses or sea-worms; according to M. le Poivre it is fish-spawn; sea-worms: according to M. le Poivre it is fish-spawn; and according to Linnseus, a kind of medusa or jelly-sah, called by fishermen blubbers or jelly-sare of a hemispherical shape, and about the size of a sare of a hemispherical shape, and about the size of a goose's egg; and in substance bear a strong resemblance to ichthyocolla or isinglass. They are gathered by the Chinese, and sent to all parts of the world, and guish the order of birds called Accipitres by Linnseus.

# Birds of Prey

are esteemed a great luxury. Mr. Marsden for great quantities of these nests in the island of Bu tra, particularly about Croe. A large cave, sit four miles up the river of that name, contains we numbers. The white nests are more valuable that the black, being found in the proportion of only size to twenty-five. Mareden says:—"The white sort sell in China at the rate of 1,000 to 1,600 Spanish dollars the pecul, the black is usually disposed of in Batavis for pecul; the black is usually disposed of in Darwisson about twenty dollars the same weight, where it is chiefly converted into glue, of which it makes a very superior kind." The same authority considers that the difference of colour is owing to the mixture of feathers with the viscous substance of which the nests are formed; and deduces that opinion from the expension of the control of the label. riment of steeping the black nests for a short time in hot water, when they are said to become in a great degree white. When the natives take the nests, enter the cave with torches, and by means of a ladde made of a single bamboo notched, ascend and pull down the nests, which adhere in numbers together, from the side and top of the rock. The more regularly and frequently the cave is stripped, the larger the pre-portion of white nests found. On this experience, the and frequently the cave is stripped, and larger the pay-portion of white nests found. On this experience, the natives destroy the old nests, that they may find white ones in their stead at their next search.—Bef. Count Hogendory's Coup d'Eil sur l'Ile de Java; and Craw-furd's Eastern Archipelago.

BIEDS OF PASSAGE are those bitds which migrate

from one country to another at certain times, depending on the seasons. Availing themselves of their proof flying, many birds remove themselves, at on Availing themselves of their power periods of the year, to places where the temperature is more congenial and the supply of food more abusdant. Even in the tropics, some birds, like the bird of paradisc, migrate from island to island, according to the change of seasons from the dry to the wet monacon. In the temperate and colder regions, however, birds of passage usually migrate from south to north or from north to south, north to south, as winter passes into summer or summer into winter. They are usually divided into two classes,—winter and summer birds of passage, the term being applied according to the time when they make their appearance. Hence the summer birds of passage in one country are the winter birds of passage in another. The approach of spring is always heralded by the arrival of summer birds of passage, and their appearance is always connected with pleasant and cheerful associations. During the winter season, large passage in one country are the winter birds of pass numbers of winter birds of passage, such as wild swans, geese, and other water-fowls, leave the frozen waters of the north and migrate to the shores of Great Britain. Woodcocks, fieldfares, redwings, and many other birds which breed in northern countries, also make their appearance regularly. The migrations of the pigeons in America are very extraordinary, on account of the vast numbers which compose the flocks. The return of some birds of passage can be depended on almost to a single day; and in some places, such as St. Kilda, where the inhabitants depend for their existence on the sen-fowl, their return is almost purousally on the same date every year. It has been observed that some birds of passage leave at the regular time, while others seem dependent upon the weather and temperature. Nearly all birds of this species have long and powerful wings; but some are anort-winged. They can pass over great distances in a very short period of time; and us they can fly with case at the rate of 50 to 150 miles an hour, they often arrive at their destination with comparative ease; but some birds, such as the woodcock, are often found much exhausted after their flight. That birds of passage return to the same places which they formerly inhabited, has been clearly proved in the case of swallows. At one time it was believed by many ornithologists that swallows hybernated; but this opinion has latterly been completely overthrown, and their annual migrations have been completely ascertained. The subject of the migration of birds is very interesting when taken in reference to the instinct which guides them. When a bird of passage is confined in a cage, or otherwise, it shows great inquietude and restlessness whenever the time of minimum of the confined in the conf

#### Birras

They have remarkably keen sight, and great perfection in the sense of smell. Many birds, however, which follow and prey upon other birds, do not belong to this order; and those which live upon fishes, worms, and insects, are not reckoned as birds of prey. There are two sections into which birds of prey are divided,—the diurnal and the nocturnal; the latter division is composed entirely of owls.

Composed entirely of owls.

BREUS, bis-rus (Gr. beros, a coat), the name given to the ordinary outer habit worn by Christians in Africa in the time of St. Augustine. In those early ages neither bishops nor presbyters were accustomed to wear any distinguishing habit but what was peculiar to all Christians; and when Eustathius adopted the pallium, or philosophic cloak, the council of Gangra decreed that "If any one uses the pallium, or cloak, upon the account of an ascetic life, and, as if there were twent holliums in that condemns those that with zero. some boliness in that, condemns those that with reverence use the birrus, and other garments that are commonly worn, let him be anathema."—Ref. Eadie's Ecclesiastical Cyclopædia.

BIRTH, birth (Ang. Sax. beorthe; Germ. burt, from the verb bæren, to bear), the act of introducing or leading into life of animals and vegetables. It is figuratively used for extraction, lineage, rank by descent. It also means to sustain or bear. A ship's station when riding at anchor is called a birth, or berth; so is the place on board in which chests, &c., are stowed, called the birth of the mess.

BIRTH, CONCEALMENT OF. (See CONCEALMENT OF

BIRTH.)

BIRTHDAY, birth'-dai .- Literally the day on which any one is born; but more generally used to designate the anniversary of that day. It corresponds with what the ancient Greeks called genethlion, and the Romans natalitius dies. Many of the ceremonies connected with the religion of the ancients were celebrated on birthdays; and the omens by which they estimated the felicity of the coming year were also taken on the same days. The birthdays of gods, emperors, poets, and great and illustrious men, were celebrated with great popp and splendour. The mode of celebrating these days was by wearing a splendid dress, and putting on rings, only worn on these occasions. The men offered up sacri-fices of frankincense and wine to their genius, and the women to Juno. Costly suppers were also provided, and treats given to their friends and clients, who, in return, made them presents, and offered vows and good wishes for the many happy returns of the same day. The birthday of Virgil was held with great ceremony by the wits and poets who succeeded him: Pliny states that Silius kept it with more solemnity than he did his own. The inhabitants of Rome and Constantinople celebrated the birthdays of their respective cities with great pomp and magnificence. The birthdays of emperors were commemorated with public sports, feasts, wows, and medals struck for the occasion. But the which they were born; indeed, the word natalis among the Romans was extended to all feast-days. Amongst the spcients, the day of their adoption was always considered as a birthday, and celebrated accordingly. Considered as a Dirthday, and celebrated accordingly. Three birthdays were observed by the emperor Adrian,—the day of his nativity, the day of his adoption, and the day of his inauguration. It was generally considered, in those times, that when men arrived at the highest honours in the state, they were born again; and the day was thenceforth celebrated as a birthday. The birthdays of the saints and martyrs denote the days of their deaths.

BIRTHS, MARRIAGES, AND DEATHS.

STATISTICS and REGISTRATION.)

BIRTEWORTS. (See ARISTOLOCHIACE E. Bis, bis (Lat., twice, or double).—The Latin root of

Bis, in Mus., a term which always implies that the bar or bars included with it in the same curve (drawn er or over the notes) are to be sung or played twice before the performer proceeds to the succeeding bar or

Bisour, bis-kit (Fr., twice-baked), a kind of bread, usually made in the form of small flat cakes. Formerly biscults were subjected to two bakings,—whence the name; but this is not found necessary at the present

## Bishop

biscuit. It is an article of very great importance or board ship, where, in long voyages, ordinary bread would become mouldy and unfit for food. Sailors biscuits are made from a dough of coarse wheat, water, and common sait. After being well kneaded, the dough is rolled out into a sheet of the required thickness for the biscuit. Each biscuit is then cut out and placed in a hotoven for a quarter of an hour. Immediately after baking, biscuits are removed to heated rooms, where they remain for two or three days, in order that all the moisture may be thoroughly expelled from them. It is for the same reason that they are all formed in the shape of flat cakes. The dough of capiormed in the shape of flat cakes. The dough of exp-tains' biscuits is partially fermented before baking, and is made of finer flour. Water-biscuits are com-posed of flour and water, with an addition of butter, eggs, sugar, or spices. There are many other varieties of biscuits; and the name is applied to several kinds of sweet cakes, such as sponge-biscuit, &c. Several of the large manufactories make more than twenty tons of hisuits weakly tons of biscuits weekly.

BISCUITS, MEAT, are made with a certain quantity of mest and flour, prepared and baked in the form of cakes. They are generally made by boiling slowly large pieces of raw meat in a small portion of witer. After a time the fat is skimmed off, and the remaining soup boiled down still further, when flour is added. The mass is then rolled out to the required thickness, and then baked and dried like ordinary ship-bisouits. Meat biscuits, when boiled with twenty times their own weight of water, and then properly seasoned, make excellent soup; and they can also be enten like ordinary biscuits. They generally contain half a pound of flour and the soluble part of five pounds of meat. They have been the means of preserving a large quantity of fresh meat, which the inhabitants of Australia and the Arrentin security was in the habit and the Argentine republic were in the habit of throwing away, as they had no market for it. Meat biscuits were first introduced into Britain in 1851, at

biscuits were first introduced into Dritin in 1004, ac the Great Exhibition, by Mr. Borden, an American.

Biscurr-ware, bis'-kit-wair.—Before porcelain or any other earthenware is dipped into the liquid glaze, it is fired to a certain extent previously, in order to render it porous and capable of absorbing water with avidity. The porcelain is called biscuit-ware after being the name have. thus once burnt. The unglazed bottles used for keep-

ing water cool are specimens of biscuit-ware.

BISE. (See ACONITUE.)

BISEOP, bish'-op, is a corruption of the Greek term episkope, which literally signifies a superintendent or inspector. It was employed both by the Greeks and Romans to designate certain civil officers who exercised some species of superintendency. On the introduction of Christianity, it came to be appropriated to ecclesiastical offices. It has long been a great question in the Church what kind of superintendency originally in the Church what kind of superintendency originally belonged to the bishop, whether it was of a church or body of Christians merely, or of a number of churches or pastors. The Presbyterians, Congregationists, and others, hold to the former opinion; while the Established Church of England and the Roman Catholics maintain the latter. In the English church the bishop is the highest of the three ministerial orders, and exercises oversight over a certain district, called his see or diocese. The bishop performs the functions of the contraction configuration conservation configurations. of ordination, consecration, confirmation, and excommuof ordination, consecration, confirmation, and excommunication. He exercises a superintendence over the pastors in his diocese in regard to their morals, the performance of their duties, &c. The bishop is elected by the chapter of his cathedral church; but the nomination is virtually in the crown. The sovereign, on a vacancy being notified, sends to the chapter a missive letter congé d'élire, that they proceed to clect a succesletter congé d'élire, that they proceed to clect a successor, at the same time naming the person they are expected to clect. If they do not proceed with the election within a short time, the king may nominate by his own authority; or, if they elect any other than the person named, they incur the penalty of a pramunire, which includes forfeiture of goods, outlawry, and other evils. A bishop must be at least thirty years of age. He is said to be installed in his bishopric, writes himself by Divine permission, and has the title of lord and right reverend father in God. The English bishops are, by virtue of their bishopries, lords of parliament, and sit in the Upper House. They

claim all the privileges enjoyed by the temporal peers, except that they cannot be tried by their peers upon indictment for treason or felony, nor at upon such trials in the court of the lord high ateward. They are seems in the court of the lord high ateward. They are also practically excluded from sitting on trials for capital offences; for they are prohibited by the canons of their church from being judges of life and death. The bishop of Sodor and Man has no seat in the Hames of Lords, and since the reconstruction of the control of the contro House of Lords; and, since the recent creation of the bishopric of Manchester, the last appointed of the other bishops has no seat (except those of Canterbury, York, London, Durham, or Winchester); so that the number of lords spiritual sitting in parliament might not be increased. In England there are in all twenty-eight bishops, including the archbishops of Canterbury and York, each of whom has his own see or diocese, in which he exercises ordinary episcopal functions. The bishops of his province, over whom he exercises a certain jurisdiction, are called his suffragans. The term originally, however, denoted a titular bishop appointed to assist the bishop of any diocese in his spiritual functions, and to supply his place when absent. The archbishop of Canterbury is styled Metropolitanus et Primus totius Anglie, and takes precedence of all the nobility of the realm after the blood royal. The archbishop of York is styled Primus et Metropolitanus Anglia, and has precedence of all dukes not of the blood royal, and all the great officers of state of the blood royal, and all the great officers of state except the lord chancellor. (See ARCHRISHOP.) The bishops of London, Durham, and Winchester take precedence of all the other bishops, who rank after them according to their seniority of consecration. There are twenty bishops in the province of Canterbury, and six in that of York. Formerly the incomes of the sees differed very much in amount; but latterly the acclesiatical commissioners have been from time the ecclesiastical commissioners have been from time to time, on the avoidance of sees, attempting to adjust their incomes. The present income of the archibishop of Canterbury is £15,000; of York, £10,000; of the bishop of London, £10,000; Winchester, £10,500 (on next voidance, £7,000); Durham, £8,000; Ely, £5,500; the others from £4,000 to £5,000, except Sodor and Man, £2,000. In Ireland there are two archbishops and ten bishops; one archbishop and three bishops, who take their seats by rotation, representing the Irish church in the House of Lords. Colonial hishoprics in connection with the established church have from time to time been created by the crown in the principal British colonies. The first of these was the bishopric of Nova colonies. The first of these was the bishopric of Nova Scotia, created in 1787; and at present the number amounts to thirty-nine. The salaries are in some cases voted by the imperial purliament from the consoli-dated fund; in others they are paid from the colonial funds, or are secured by bequests or contributions from the colonial bishoprics fund, or other charitable funds; or they are made up from two or more of these Church in Scotland; viz., of Edinburgh; Argyll and the Isles; Brechin; Moray and Ross; St. Andrew's; Dunkeld and Dunblane; Aberdeen; Glasgow and Galloway. There are fourteen Roman Catholic bishops in England, four in Scotland, and four archbishops and twenty-four other bishops in Ireland.

Bishor, a heverage composed of hot or cold bur-undy, claret, or other red wine, poured upon ripe bitter oranges, and then adding sugar and spices according to taste. It is drunk either hot or cold, and its quality depends entirely upon the excellence of the wine employed. In order to make bishop properly, the oranges ought to be well selected, and the white the oranges ought to be well selected, and the white part between the peel and the pulp rejected. It is called cardinal when made with white wine, and sope when made with tokay. Its present name was bestowed upon it in the 17th century; but it was known, under other names, in Germany, during the Middle Ages. It was imported into Germany from France

and Italy.

Bergor, Boy. (See Boy Bishor.)

Bishor, Boy. (See Boy Bishor.)

Bishorhor is convalent to see or diocese, and denotes the district over which a bishor's superintendense extends. At the time of the Conquest there were two archbishoprics and thirteen bishoprics in Brighad. In the reign of Henry I. two new bishoprics were formed,—Ely and Carlisle. To these Henry VIII. added six new bishoprics, viz., Westminster, Chester,

Cloucester, Peterborough, Bristol, and Oxford; but the see of Westminster was soon afterwards usited to that of London. From that period down to 1898 me-change was made in the diocesan distribution of England; but by 8 & 7 Will. IV. c. 77, a new bishopric was created, and the union of the bishoprics of Bristol and Gloucester provided for; and by 10 & 11 Vict. c. 108, the bishopric of Manchester was created. No change appears to have taken place in the distributions of the four bishoprics of Wales,—those of Bangor and St. Asaph in North Wales, and of St. David's and Llandaff in South Wales; and the bishopric of Man is said to date from the 5th century. At present, the province of Canterbury comprises the bishoprics of Canterbury, Rochester, London, Winchester, Norwich, Lincoln, Ely, Chichester, Salisbury, Exeter, Bath and Wells, Worcester, Linchfield, Horseford, Llandaff, St. David's, Bangor, St. Asaph, Gloucester and Bristol, Peterborough, and Oxford. The province of York comprises the bishoprics of York, Chester, Durham, Carlisle, Ripon, Manchester, and Sodor and Man. c. 108, the bishopric of Manchester was created. and Man.

Bisnor's, or Consistory Court, is an ecclesiastical court held by the bishop's chancellor or commissary in his cathedral church, or other convenient place in his diocese, for the hearing and determining of matters and causes of ecclesiastical cognizance happening within his diocese. An appeal lies from the decisions of this court to the court of the archbishop of the province. The functions of the bishop's court are now rarely called into action, as proceedings against the benefited clergy now take place under the Church Discipline Act, 3 & 4 Vict. c. 86, and against curates under 1 & 2 Vict.

BISMILLIN, bin-mil'-la (Arab.), a solemu phrase made use of by the Mahometans at the commencement of all their books, &c. It signifies "in the name of the most merciful God."

BIBMUTH, biz'-muth (Ger. bismut), in Chem., symbol Bi; atomic weight 213; specific gravity 9.8,—a metal of a greyish-white colour, with a strong characteristic tings of red. It is hard, brittle, and but slightly malletings of red. It is nard, prittle, and but signify manifolds. It flues at 507°, and is obtained in fine cubical crystals by slow cooling. The peculiar property it possesses of expanding as it cools, renders its alloys of great use to the typefounder and die-sinker. It also increases the fusibility of other metals with which it is united. The remarkable alloy known as "fusible metal" metal" contains one equivalent of bismuth, one of lead, and two of tin; fuses below 212°, and, by a car-tain admixture of cadmium, can be melted at a still tain admixture of cadmium, can be melted at a still lower temperature. (See Cabrium.) It is also occasionally employed in cupellation, and some of its compounds are used as pigments, the hydrated czychloride being used as a cosmetic under the name of peartwhite. Bismuth occurs in nature principally in the metallic form in the clay-slate and gness formations, its principal source being Schneeberg, in Saxony: its also found in Cumberland and Commell. Rismeth is also found in Cumberland and Cornwall. extracted from the ore by heating it in inclined cast-iron tubes with cups attached. The tubes are brought which are at the lowest part of the incline. Biamuth forms two exides,—the teroxide, BiO<sub>3</sub>, and an acid oxide, BiO<sub>4</sub>, or bismuthic acid. Teroxide of bismuth may be obtained by heating the nitrate to low redness: if is a yellow insoluble powder. The hydrated teroxide, which is white, may be obtained from a salt of bismuth by precipitation with ammonia. Biamuthic acid, or peroxide of bismuth, is formed when hydrated teroxide of bismuth is digested with a concentrated solution of potash, through which chlorine is passed. A red of potash, through which chieffer is percentian of bismuthate of potash is formed, and s red precipitate falls to the bottom, which, on being well washed and digested in cold nitric acid, leaves behind washed and digested in cold nitric acid, leaves behind a red powder, which is the hydrated acid. Nitrate of bismuth is prepared by dissolving the metal in dilute nitric acid with the aid of heat, which gives rise to four-sided prisms, which are decomposed by water into an acid nitrate, which remains in solution, and as basic nitrate, the trientirate of bismuth, falls as precipitate. It is used as a pignostate conductory of bismuth. The other compounds of bismuth are too unimportant to be described. Bismuth occurs in

mature associated with cobalt, eiver, tin, and areenic; also as an oxide, in bismuth other; as a sulphide, in bissuffine, or bismath planes; as an arsenide, a carbonate, ad a cilicate, in bismath-blends.

Brow, bl-see (Lat. Bos Bonasses).—The principal uropean regions where this animal is found are the against forests of Poland, the Carpathian mountains, at Lithusms. Its chief abiding-place in Asia is in the ghbourhood of Mount Caucasus. It is as large as a English bull, but looks much larger, on account of a wealth of shaggy hair, and is ten times as formidable, because of its tremendous strength and intense fero-city. Its head is small; its horns short, sharp, and strong; and its eyes red and flery. The colour of its biroug; and its eyes red and flery. The colour of the birde is rufous-brown. The American bison (Bos assertions,), commonly called the American buffulo, is birger, shaggier, and flercer even than the European species. The hair about its neck and shoulders is bushier, and of a fine texture. The hump, which is colong, diminishes in height towards the tail, lending chlong, diminishes in height towards the tail, lending a considerable obliquity to the outline of the back. On she crown of the head the hair rises in an immense see, and shows in thick, close curls before the horns; Selow the chin the hair grows like a beard, and falls as low as the knees. According to Catlin, and other travellers in North America, this maned buffulo affords travellers in North America, this maned cummo amorus meet only food, but every creature-comfort to three hundred thousand people. Its flesh is their meat; its skin serves them for coats, and beds, and boots; and walls for their tents, and tiles for the roof; and for saddles, and bridles, and lassos. The bones are converted into saddle-trees, into war-clubs, into whistles, and into musical instruments. Of the horns are made pins, needles, ladles, spoons, and spear-heads; the miseur serve as strings to their bows, thread to stitch their buffalo-robes and to form their tent-cloths, and we the attachment to their persons of scalps and such dessing nic-nacs as they may set store by. pleasing nic-nacs as they may set store by. The bison's feet and hoofs, when stewed down, yield a superior gine, largely used in the construction of hunting-spears and arrows. The mane of the animal is twisted sto ropes and horse-halters, and the tuft at the extre-sity of its tail is used as a fly-brush. The brains even re not wasted, but used in the preparation of leather from the bison's hide. The number of bisons roaming he wast North American prairies is said to grow less year by year; still herds consisting of thousands exist at the present writing. During the pairing season, the roaring of the bulls is terrific, and the combats that take place between them are unequalled even among the carnivors. They swim broad rivers in erly the same order as they traverse plains, viz., a dense animated mass, pressing so close at each others heels that the foremost dare not stop from peril of being trodden to death. The Indians profit by this peculiarity, and, ereeping up to a herd, drive them forward, with hideous shouts and yells, to the verge of a precipice, over which a score or so will certainly

BISERVILE, bis-sex'-til (Lat. bissextilis, from bis, twies, sentilis, einth), in Chron., is the name given to that year which contains 366 days, called, also, leapyear. In the Roman calendar, as reformed by Julius Casar, the length of the year was fixed at 3652 days; ut in order that the year should always begin with the beginning of a day, it was directed that every fourth a should have an additional day, the others having year should have an additional day was given to February, see being the shortest month, and was inserted between the 24th and 25th. By their mode of reckoning, the 24th was the sixth day before the calenda, or lst of March, hence called sexto calendas Martii; and in order to preserve the same enumeration, the interconter 20 preserve the same enumeration, the inter-culary or repeated day was termed bisectus dies, or the second sixth day, and the year in which it occurred bisectitie. In legal reckoning as to the birth of a child, the two sixth days were regarded as one. In our reckoning, the interculary day is made the 29th of

Bistoper. (See CLENDAR.)
Bistoper. (See POLICOUR.)
Bistoper, bis-too-re (Fr. bistoire), in Surg., is a small custod back ased for opening abscesses, and for

of wood: beenhwood is considered the best for purpose. The following is the method of prep purpose. The following is use meaned or preparing the pigment. Infuse a pound of the soot in two quarts of water, and boil it for thirty or forty minutes; the mixture must then be allowed to estile, and the clear firid poured eway from the sediment that has collected at the bottom. The liquid thus obtained must be at the bottom. The liquid thus obtained muss be evaporated until what substance there is remaining in this is called bistre, and is vessel is perfectly dry : this is called bistre, as made into cakes for water-colour painting by the addition of a little gum-water. Bistre is used in the same way as Indian ink and sepia for making water-o drawings to show the effect of light and shadow.

Brr, or Brrr, bit, in Mar, strong but short pieces of timber projecting vertically from the deck of a vessel, in the fore-part, close to either side, and strongly secured to the beams on which the deck-planks are laid. They are placed in pairs, and are principally used for fastening the cable when the ship is at anabor or moored alongside a quay. There are many kinds of bitts used for different purposes in shipbuilding,

and distinguished by various names.

BITTER-ALMOND OIL is a pharmaceutical product obtained by the distillation of bitter simonds with water. Martraès discovered it in 1803. The amygdaliferous portions of most Pomea, Amygdalea, the leaves of cherry-laurel, cherry kernels, peach, &c., yield the product. "The oil is thus prepared: Bitter yield the product. I also of its thus prepared; I have almonds are crushed, and freed from fixed oil by cold pressing; then stirred up to a thin paste with 4 to 6 parts of cold or lukewarm water, and the mixture allowed to stand for twenty-four hours before distallation. If distilled over the open fire, it is very apt to froth over, unless it is stirred continually; for this reason it is best distilled with vapour of water. may be done by covering the bottom of the still with a thick layer of coarse sand saturated with water, and pouring the almond paste upon it. The frothing may also be arounded by removing most of the solid matter before distilling. The first portion of the distillate is richest in oil, and in hydrocyanic acid also, and is therefore clear; the latter portions, containing less hydrocyanic acid, are milky. The distillation is con-tinued as long as the liquid which comes over smells of bitter simonds; the oil in the receiver is then separated from the water. The addition of chloride sodium facilitates the separation of the oil. 1,000 parts almonds do not yield more than 7 or 8 parts oil."

—(F. J. Conington, in Watts's Diet. of Chemistry.) Bitter-almond oil was at one time very much used in perfumery, and, being an expensive product, it is much adulterated. The adulterants are chiefly alcohol, some light ethereal oil, or nitro-benze, which last has in a great measure replaced the almond oil. "Light oils, whose smell is masked by that of bydride of b zoyl may be detected by allowing the latter to exidine into benzoic acid by exposure to the air, when the ameil of the former becomes avident; or by their effect, or the specific gravity of the oil, a method which applies to alcohol also. Alcohol may also be detected by agitating the oil with twice its volume of nitric said of specific gravity 1:42; with unadulterated off no imspecific gravity a net with unantitation and animaliate action is produced, but if 8 to 10 per cent, of sleohol be present, red funes are given off with affer-vescence. By using acid of 15 specific gravity, as little as 3 to 4 per cent, of alcohol may be detected. vescence. By using soil of 1 to specing gravity, as little as 3 to 4 per cent of alcohol may be detected. (Redwood.) A good re-agent for detecting adulterations is a strong solution of an acid sulphite of alkalimetal, which dissolves the pure oil entirely, but leaves behind all impurities which are not of the nature of aldehydes."—Watris's Dict. of Chemistry.

BITTER-ALMOND WATER.—Water containing a column of the oil of bitter almonds. It is prepared in

various ways. Sometimes a solution of the oil in spirits of wine is added to water; sometimes it is prepared by distillation with water, which is the best mode; but often it is obtained by mixing magnesis with the essentital oil, and adding it to the water. Laurel-water and cherry-water, the former prepared from laurel-leaves and the latter obtained from wild cherries, contain the same constituents as bitter-almend water.

regions skirting the Mediterra-neal, in China, India, and even in Southern Africa. It was formerly plentiful in this country; but the universal drainage of marsh land has driven to seck 21 locality more congenial to its When nature. alarmed, the bittern emits a pe-culiar cry, by no means pleasant to hear; but on means the approach of the breeding season the sounds it

BITTERN.

utters are of the most hollow and melancholy kind. The provincial English names are "Mere-drum." "Night-raven," and "Bull of the Frog." On the ht-raven," and "Bull of the Frog." On the be visible. " Most, if not all, the birds of the genus, especially our common heron, have on breasts a considerable space void of feathers, filled up by tufts of down, to which adheres a sort of clammy oily substance. It is not, therefore, unlikely that this oily matter may, either by smoothing the water or in some other way, enable the bird to attract, or, when attracted, to strike its prey with greater certainty."—(Stanley's History of Birds.) The length of the common bittern is about thirty inches, and its voracity remarkable. Mr. Yurrell found in the atomach of one the bones of a good-sized pike. The little bittorn is also a summer visitor to these islands, and is the smallest variety of the lamily to which it belongs known in Great Britain. It is an inhabitant of a wide range of countries, as it has been met with in south-western Asia, in Holland, Germany, southern France and Italy, and even as far north as Sweden. The

Bittern, bitt-tern (Du. butoor) (Botaurus stellaris). American bittern is somewhat smaller than the common bittern bird is generally found throughout the entire mon bittern. On the other side of the Atlantic this bird Eastern hemisphere. In summer it chiefly affects the north of Europe and Siberia, at other seasons the mild habits,—being called, among other titles, Indian-billet, mon bittern. On the other side of the Atlantic this bird has different names in the different states which it inhabits,—being called, among other titles, Indian-billet, Indian-hen, and Dunkadoo. The bittern once afforded great aport to falconers in England, and it was protected by severe penalties. Any one who destroyed or took away the eggs of a bittern was liable to a year's imprisonment and a line of eightpence for each egg, by a statute of Henry VIII. Yarrell, in his History of British Birds, informs us that "the bittern was formerly in some estimation as an article of food for the table. The flesh is said to resemble that of the leveret in colour and taste, with some of the flavour of wild fowl." Sir Thomas Browne says that young bitterns were considered a better dish than young herons. Turning to Yarrell once more, we find that " the bittern constantly feeding at night, is, therefore, seldom seen on wing in the day, but remains with head erect in thick beds of reeds, or conceals itself among flags, rushes, or other rank aquatic vegetation which afford it a solitary and secure retreat: "from such situations it is with difficulty made to take flight; and when at length obliged to get on wing, the pace is dull and flag-ging, and seldom sustained to any great distance. M. Viellot says that in France it is occasionally found in woods. Neither females nor the young differ much in their plumage from the male bird.

BITTERN, the mother-liquor left after the extraction of salt from sea-water by crystallization. It con-tains sulphate of magnesis, or Epsom salts, in large quantities, and is one of the principal sources of the

BITTERS, bit'-ters (Ang.-Sax.), the common name for au infusion of bitter herbs, which is consumed in large quantities as a stomachic, generally mixed with ardent spirits. The plant usually selected for the proparation of bitters is the garden ingelics (see ARCHARGELICA), Camomile-flowers the reots and seeds being used. coriander-seeds, and other vegetable tonics and stimulants, are occasionally employed.

BITTERSWEET. I See SOLANUM.)

BITTERWOOD. (See XYLOPIA.)
BITUHEN, bit'-n-men (from Gr. pitus, the pitch-tree,
because it resembles pitch), is a term which includes many fossil bodies of a resingua macra. True bitunes is fossil tur, and is the product of the action of an alevated heat upon vegetable bodies. The surrounding vated heat upon vegetable bodies. stratum, which is generally tertiary, is mostly impregnated with bitumen, giving rise to bituminous clay, shals, or coal, according to its nature. In many cases, bitumen occurs in nature as a regular deposit, forming beds like true coal. Lignites (which see) contain bitumen imbedded in them in small quantities. Asphalt is a finer sort of bitumen, much used in the preparation of paving-material. Bitumen is closely allied in its or paying material. Buttern is crosely aimed in its produced by the destructive distillation of coal. (See ASYMALY, PETROLEUM, COAL-TR.) The first process for obtaining pictures by means of light was founded upon the fact that the bitumen of Judes when exposed to the sun's rays became insoluble in oil of lavender, whilst those parts remaining in shadow preserve their solubility. This process has of late received a modification by which it has been applied to the purposes of photolithography, or engraving on stone by means of the sun's rays.

BIURET, bi'-u-ret (Lat. bis, twice, and urea, a chemical principle of urine), a compound, prepared by exposing ures to a temperature of 300° Fah. It has the exact composition of bicyanate of ammonia, and bears the same relation to that substance that ures does to

cyanate of ammonia

BIVALVE.

BIVALVE, bi'-valv (Lat. bis, double, valve, valves),
in Conch., a term given to those
kinds of shell-fish which possess two shells, in contradistinction to those which possess but one, and which are termed univalve. (See Mor-LUSCA.) As familiar examples of bivalves may be mentioned the mussel, cockle, and oyster. Bivalve shells form the testaceous envelope of mollusks, and are composed of two concave plates connected by a baving an elastic liga-

Bivovac, biv'-on-ak (Ger. beiwachen or bewachen, to watch over), in Mil., a term formerly applied to videttes of cavalry thrown out as outposts to watch the movements of the hostile force, and to prevent any attempt at a night attack. From the circumstance of these videttes passing the night in the open air without any protection, the word was at last taken to signify the state of an army passing the night on the field without tents or any kind of shelter. The practice was commenced by the French soldiery during the wars that followed the French revolution, who, for the most part, were without tents and the incumbrance of baggage, remaining on the field en bicouac, as they termed it, that their movements from place to place might be made with greater rapidity. Their example was aftermade with greater rapidity. Their example was afterwards generally followed by the European armies, and by the English in the Peninsular war; but it is pre-terable to provide shelter for the soldier in the shape of tents or huts whenever it is practicable, as his health suffers from exposure to the night air, and cold and wet, especially in the early part of a campaign. troops are in a bivouse, rows of large fires are lighted at intervals, round which the men group themselves, after piling their arms. These fires are kept up through the night, and the country around is searched for straw, on which the soldiers lie, after contriving some temporary shelter of loughs or boards, if they can be procured, to keep off wind and rain. Allowing about a dozen men to each fire, the fires of a biyoung sometimes afford the enemy the means of calculating the numbers of the force to which they are opposed .-Ref. English Cyclopædia - Arts and Sciences.

BITACEE, or FLACOURTIACEE, bix-ai'-se-e, in Bot.,

a nat. ord. of dicotyledonous plants in the sub-class The the sub-class contained the sub-class with internate leaves, usually entire and leathery, and very often dotted. The flowers are polypetalous or apetalons, the stamens being hypogynous, and equal in number to the petals, or some multiple of them. The fruit is one-celled, dehiscent or indehiscent, having a truit is one-celled, debiscent or indehiscent, having a thin pulp in its centre. The seeds are numerous, usually enveloped in a covering formed by the withered pulp. The plants of this order are almost confined to the hottest parts 22 the East and West Indies and Schrick. There are 34 genera and about 90 species. Many are feebly bitter and astringent, and have been used as stomachies. The bark of aphloid is said to be

emetic. The fruits of Oncoba and of some species of Placourie are edible and wholesome. The most important plant of the order is Bira orelland, which yields a red dye. (See Annarto.) The reddish purportering the seeds is the source of this colouring

BIXIN, bix', in (from bixa, the name of the tree whence annatto is derived), an orange-red colouring matter, found in annatto, to which it owes its dyeing matter, found in annatto, to which it owes its dyeing properties. It is a resinous substance, soluble in shoohol and ether, but sparingly so in water. The sikalies dissolve it, producing a deep red colour, but, on neutralizing, it falls as an orange precipitate. It is also soluble in fixed oils.

BIZARRE, be-zar' (Lat. bis, twice, and various, to vary), is a term derived from the French, and signifying odd, capricious, or fanciful. A person is said to be bizarre when his character, tastes, or opinions are incessantly changing and differing from those of other men, and who is characterized by attempting always to say and do what is singular. Bizarre is also applied to

something that is extraordinary or singular.

Bizarre, a term applied by floriets to a carnation with a white ground, marked with two or more colours.

(See DIANTHUS.)

BLACK, blak (Sax. blac) .- The total absorption of all the rays of light constitutes black. (See Colours, Light.) Amongst the mediæval illuminators, black signified evil, error, and wee; and the figures in their paintings are represented in black drapers when any of these subjects are portrayed. Thus, in the picture of the Temptation, Christ is represented in black robes. In heraldry, black, or sable, is symbolical of wisdom or prudence. From very ancient times, black has been worn as the emblem of mourning. In some of the Oriental countries, black is looked upon as a badge of servitude or low birth. The principal black pigments used in the arts are generally composed of carbon. They are vegetable blue-black, ivory-black, cork-black, and lamp-black.

BLACK ACT .- Previous to the statute 9 Geo. I. c. 23, the king's forest near Waltham, in Hunts, was infisted by lawless persons, who disguised themselves and blackened their faces, and were hence called Waltham blackened their faces, and were hence called Waltham Blacks. They committed great devastations on the deer; to prevent which, and similar offences, the statute enacted that persons bunting, armed and disguised, and killing or stealing deer, or robbing warrens, or stealing fish out of any river, &c., should be guilty of felony without beneft of clergy. The act was repealed by the 7 & 8 Geo. IV. c. 27.

BLECK LIVE. (See RELIVERS)

BLACK ALDER (See RHAMNUS.) BLACK ANT. (See ANT.)

BLACK ART, a name given to magic, as it was superstitiously imagined that all who exercised the art were aided by the devil in the accomplishment of the effects produced. As the pursuit of magic was deemed suiful in the extreme, and black was the emblem of wickedness and evil in the Middle Ages, so the term "black art," became applied to it. (See Magic.)

BLACK ASR. -Impure sods, contaminated with sulphide of calcium, charcoal, and other impurities, formed in the manufacture of soda from sea-salt. By lixiviation, filtration, and evaporation, the ordinary

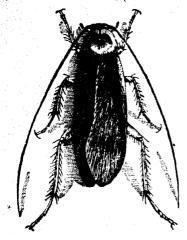

BLACK ASSIZE is the name given to an assize held in the old town-hall of Oxford in 1577, on account of an extraordinary and fatal pestilence which broke out during it. It is said that judgment had just been passed upon one Jeneks, a bookbinder, for sedition, who was sentenced to lose his ears, when there arose such an infectious damp or breath among the people. that many were then smothered, and others to deeply infected, that they lived not many hours after. Above 600 sickened in one night: and, from the 6th of July to the 12th of August, 510 persons are said to have died in Oxford and the neighbouring villages. It was popularly regarded as a divine judgment on the cruelty of the sentence. but it was of the sentence; but it was probably owing to the filthy condition of the neighbouring good where the prisoners had been kept. A similar pestilence is said to have broken out at Cambridge during an assize held there in 1521.—Ref. Anthony is Wood's History and Antiquities of the University of Oxford.

BLACK BAND, a clayey carbonate of iron found in

# Black-Beetle

Septland. It contains sufficient carbonaceous matter to allow of its being calcined without any additional fuel. It is found principally in the Socto coal-fields, and is the most important ore of iron in those districts.

BLACE-BEETLE, be tel (Blatta orientalis) .- These inaccis, though now common throughout Europe, are supposed to have been originally natives of India, and, by the progress of commerce, carried thence westward. On board merchant-ships the black-beetle is very commonly found; and it is said to be more plantiful in seaport-towns than other places. Their plentiful in seaport-towns than over purchashis are too unpleasantly familiar to us all to need habits are too unpleasantly familiar to us all to need description here. All sorts of matter, vegetable or animal, suits the appetite of these insects. The curious way in which insects of this genus lay their eggs is

BLACK-BEETLE.

worth mention. Instead of emerging singly from the shdomen of the female, they are inclosed in a horny case almost half as large as the abdomen of the parent. Within this the eggs are ranged in two rows, separated by a partition which runs down the middle of the case; each egg is also separated from the next by a similar egg is also separated from the next by a similar tion. This egg-case is attached to the wall or floor with a strong adhesive liquid furnished by the mother. When the larvæ are hatched, they emit from their mouths a fluid which dissolves the walls of their prison, and they are set free. The extrusion of the ponderous egg-case is sometimes a difficult matter with the mother; and she may be sometimes seen labouring about, and presenting the disagreeable appearance of

grasses. It lays five eggs, generally of a light bine. There is sometimes, however, so little difference be-tween the eggs of the blackbird and the comment thrush, as to make it impossible for any one but as accomplished ornithologist to distinguish between them.

BLACE BOOK OF THE ENGLISH MONASTREES was a

BLACK BOOK OF THE ENGLISH MONASTREINS WAS B book compiled by order of the visitors of these establishments, under the reign of Henry VIII. It detailed the scandalous enormities practised in the religious houses, with a view to blacken their character, and to hasten their dissolution. Hence the phrase "to set one down in the black book."

BLACK BOOK OF THE EXCHEQUER.—The Liber Niger Scaccurii, or Liber Niger Parvus, appears to have been compiled in the reign of Henry III., and is now preserved among the other records of the Exchequer: It gives a description of the court of England as: it stood in the reign of Henry II.; the rank, wages, powers, and perquisites of the different officers of the court; the revenues of the crown, will of Henry II. &c. It has been printed by Hearne, Oxford, 1728.

BLACKCOCK, bluk'-kok (Tetrac tetrax), a species of the Grouse family, rarely seen in England, but abundant in Scotland. In its habits the blackcock closely resembles the capercalzie, inhabiting the low-BLACK BOOK OF THE EXCHEQUES. - The Liber Niger

lying districts, and feeding chiefly on the young shoots of shrubs, and seeds, and berries. According to of shrubs, and seeds, and berries. According to Yarrell, in the winter time the bird's crop is frequently

BLACK DEATH is the name given to a most destruc-tive pestilence, which, towards the middle of the 18th century, extended itself over all parts of the known world. It took its name from the black spots which appeared on the skin. It was an intense form of the oriental plague, and, like it, was characterized by buboes and carbuncles. It is said to have taken its rise in China, and to have thence travelled westward to Europe, where it made its appearance in 1348. Some accounts state that the impure air was actually visible as it approached with its burden of death. Historians of that time give a most horrible picture of the sufferings and deaths that were occasioned by it. In Europe alone, during the three years that it prevailed, it is said to have carried off 25,000,000 persons, London having lost over 100,000. It was looked upon as a judgment of Heaven; and many thought to save themselves by giving their goods to the Church, or by personal chastisements. The Jews were also looked upon as the cause of it; and, in consequence, great numbers of them suffered death. In the city of Mayence alone 12,000 of them were cruelly murdered. The black death has several times made its appearance in Europe since that time, but never with the same virulence. Boccacio, in the introduction to his "Decameren," has given a lively description of its physical and moral effects in Florence; and a full and interesting account of it is to be found in Hecker's Epidemics of the Middle Ayes.

BLACK-FLUX, blak'-flux, a compound, containing carbonate of potash mixed with carbon, much used in the laboratory as a reducing or deoxidizing agent. It is prepared by heating tartrate of potash (cream of tartar) in a covered vessel until a charred mass remains.

(See BLOWPIPE.) (See DOMINICAN FRIARE.)

Black Watch

one. In the journeys of the families to which aged, they usually rade in the earts with the listing; and people in derision gave them a of blackgrands. The

L. difficulty, the term given to the place at in which soldiers undergo short terms possible that is which soldiers undergo anort terms impressionants for minor offences against military similars; and hance applied to the old village "lock-"," or "leage," the cells of a police-station, or any on in which persons are temporarily lodged in mance. In history, the "Black-hole of Calcutta" is a place, about 18 feet square, lighted and vented by two small windows several feet from the band in "skip 146 Regists merchants and soldiers. md, in which 146 English merchants and soldiers, The belonged to the garrison and factory that had been salely established at Calcutta, were imprisoned by maker of the Nebob Surajah Dowlah, on the evening of Jane 18, 1756. These unfortunate men, suffering want of air, unbearable heat, and intense thirst, and exhausted by the continual struggle to reach the sastew air-slits, sank one by one through the long sastew air-slits, sank one by one through the long sastesse and renewal of existence to twenty-three only, who had existed through the horrors that had caused the death of their fellow-sufferers.

BLACKING, blak - ing . - The manufacture of this familiar article is of comparatively recent date. The Romans, however, appear to have had a composition similar to that known at the present day as "dubbing." In digging the foundation of the new Royal Exchange, In digging the foundation of the new Royal Exemange, pieces of Roman leather were found, imbued with a substance skin to car modern blacking. Blacking consists principally of bone-black, sugar or treadle, sperm-oil, oil of vitriol, and strong vinegar. According to Mr. W. C. Day, the method of making the famous "Day & Martin's" blacking is as follows:—The bone-black in the formal control of the production black in a state of powder is mixed with the sperm-oil mutil the two are thoroughly incorporated. The sugar or treacle is then mixed with a small portion of the vinegar, and added to the mass. The oil of vitriol is next added, and when all efference has ceased, vinegar is poured in, until the mixture is of a proper e. This constitutes the liquid blacking of Day & Martin, by the manufacture of which thousands of pounds have been made by themselves and their Paste-blacking is made in the same way, eendante. sept that the last portion of vinegar is not added. To give some notion of the business carried on by this rm, it may be stated that as many as one thousand mer bottles are sent out daily. BLACK-JACK, sulphide of zinc, or zinc-blende

(See Zanc.)

BLACK-JACK, a vulgar term for a drinking-cup of tin mned over, formerly much used in England.

BLACK-LEAD.—The common commercial name for splate, or plumbago, given to that substance from metallic leaden-grey lustre. It is, however, nearly combon, and coutsins no lead. (See GRAPHITE, Presented, Carbon.)

BERNAGO, CARBON.)

BLACK-MAD PENCILS.—The manufacture of blackmed pencils was at one time almost exclusively conmed to this country, from the circumstance that the
est black-lead was found at Keswick, in Cumberland,
say, in pieces sufficiently large for cutting into pencimedias. The invention of Mr. Brockedon, for proag large blocks by compression, has of late greatly ided this important manufacture. By compressattended this important manufacture. By compress-age mass of finely-powdered pure black-lead, without any comenting substance, Mr. Brockedon procures blocks hard enough to be sawn into the square prisms which, when placed in grooves in wood, form the block-lead reneils of commerce. By adding portions of very finely-ground clay, black-lead of different shades is formed, varying from the triple H of the engineer, the mark of which is hardly perceptible, to the quadruple B of the artist, fit for filling in the deepest shades of the decimal B. W. Brockedon's process all nearly had become B. W. Brockedon's process all nearly had become B. W. Brockedon's process all nearly had become B. of his drawing. By Mr. Brockedon's process all posregard to an impalpable powder. A good black-lead and should make a perfectly even mark,—one will effect the control of the co traily effects of the latter material, proves that the leader sphingston of the latter material, proves that the leaders here adulterated with soot, lamp-black, or, as is

enerally the case, with sulphids of authors t substitute for Camberland load is that fr Bohemis and Bavaria. It is also found at Rhodes, in Behemie and Bavaria. It is also found at Rhodes, in France, in Spain, Ceylon, and Mexico; but is not warry inferior quality, being hard, gritty, and difficult to grind. By the process of Professor Brodie the most powder with great case. The mineral is counsely powdered and mixed with 4th of chlorate of potas), to which mixture is added twice its weight of sulphuris acid. Ohloric acid is disengaged, and, after the mass has cooled, it is well washed, dried, and heated to redness. During the latter operation, the plumbage swells and becomes reduced to so fine a powder that it will swim upon water. it will swim upon water.

BLACK LETTER is the name commonly given in this country to the old English or modern Gothic letter. What are called Roman letters were employed in the writings of Western Europe from the 5th to about the close of the 12th century, when the Gothic characters came to be adopted. When printing was first introcame to be adopted. When printing was first intro-duced, the object was to imitate writing; and the first printed books were dispessed of as manuscripts, the imitation being so perfect that it required great discrimination to distinguish the printed from the written. Books printed before the year 1500 are generally in the black-letter characters, when, in most European countries, they came to be supereded by the Roman. The old Gothic is still in general use in Germany, but now many books are printed there also in Roman characters. Books in the black letter are highly prized

by antiquaries and bibliomaniaca, as being the earliest.

BLACK LIST is a name popularly given to certain
printed lists privately circulated among subscribers,
giving lists of insolvents and hankrupts, protested bills, judgments for debt, and other matters affecting the credit of firms and individuals, and intended for the guidance of merchants and others in trade. The best-known of these are "The Mercantile Test," and "Perry's Bankrupt and Insolvent Weekly Gazette."

Black Mail.—Previous to the rebellion of 1745, the

Highlands of Scotland were in a very lawless condition. The stealing and carrying off of a neighbour's cattle was a system of plunder practised even by persons of standing and influence. To obviate this state of things, a class of men rose up who professed to take upon themselves the duty of protecting the property of individuals, upon payment of a certain annual sum, which was called "black mail." They generally also They generally also took care that the cattle of those who refused to pay black mail should be carried off. When, however, any one of the payers of black mail lost his cattle, the levier either recovered them or made them good. celebrated Rob Roy was a notorious levier of black mail in the western Highlands. After the rebellion, the law was more vigorously enforced in the Highlands, and black mail ceased.

PLACE ROD, USHER OF THE. (See USHER OF THE

BLACK ROD.)

BLACK ROOD OF SCOTLAND, in Scottish Hist., is the name given to a golden cross about a span long, elaborately wrought in the form of a casket, and containing what was believed to be a piece of the true cross. It was brought to Scotland by Margaret, the Anglo-Saxon princess, on her marriage with Malcolm Ceanmore, about 1070, and came to be regarded with great veneration by the people. It was taken possessing of by Edward I of England, in 1291, but was authorquently When David II. invaded England, in 1346, restored. When David II. invaded England, in 1346, he carried the black rood along with him; and, on his defeat by Sir Ralph de Neville, it became the property of the conqueror, who deposited it in Durkam Cathedral, where it remained till the Reformation, but subsection. quently disappeared .- Ref. Chambers's Encyclopædia.

BLACKTHOEN. (See PRUNUS.)
BLACK WAD.—A dense black earthy mineral used as a pigment, also in glazing pottery, and in the manu-facture of glass and chlorine. It is a hydrated per-oxide of manganese mixed with various impurities.

DIAGE of manganese mixed with various impurities.

BLACK WATCH.—The body of men so called were regularly enrolled, about 1729, for the purpose of watching the disaffected Righlanders, who were seeking an opportunity to renew the revolt against the government of the house of Hanover in the person of George II., which had been previously attempted in

1716, a twelvements after the accession of his father, George L. A few Highlanders had been intrusted with arms by the government about four years previously, but a greater number were now enlisted from the Campbells, Grants, and other clans well affected towards the government, and divided into six companies, here of 100 men each, under a incutenant. As these men wore tartans consaining of dark colours, they were called the Black Watch. In 1739 these companies, which had hitherto acted independently of each other, were incorporated into the famous 45nd ragiment, the command of which was given to the earl of Crawford. They were then relieved from the duty of watching the Highlanders, who took the opportunity to organize the rebellion of 1745.

Bilinks, blad-der (Sax. blader, from blauca,

BLIDDER, blad'-der (Sax. blader, from blawas, to blow), in Anat., is a thin membranous bag, which serves as a receptacle for the urine secreted by the kidneys, until it is voided through the urethra. It is strated in the sy the kinneys, until its voiced infrougation treature.
It is situated in the pelvis, and is kept in its place by ligaments, which are usually divided into true and false, the latter being formed of folds of the peritoneum. It is composed of three costs or membranes, the external or fibrous membrane, the middle or muscular membrane, and the internal or mucous membrane. Its figure is nearly that of a short oval. It is broader on the fore and back than on the lateral parts: broader on the fore and back than on the lateral parts; rounder above than below, when empty; and broader below than above, when full. It is divided by anatomists into the fundus or upper portion, the body, and the neck,—that portion which is constricted by a sphincter muscle, and communicates with the urethra. On each side, rather below its middle, it receives the two ducts called ureters, which convey the urine from the kidneys into the bladder. The bladder, like every other wears of the body is liable to carryin disease. one of the most common of which is inflammation, or systitis. It chiefly affects the mucous coat of the one of the most common or which is inhammators, or cystitis. It chiefly affects the nuccous cost of the bladder; but all the other costs may be implicated; and it is either chronic or scute. The scute form is known by great pain in the region of the bladder, attended with fever and hard pulse, and a frequent and painful discharge of urine, or a retention. The disease runs its course with rapidity, and subsides, or carries off the patient, in a few days. It is to be treated by local bleeding and hot fomentations, to-gether with opiates. The chronic form of this disease is best treated by tonics and sedatives. The causes of this disease are various. It often arises from calcarious secretions, which in that case must be removed. (See LITHOTOMY.) Irritability may exist in the bladder, unaccompanied by inflammation, and may arise from over-distention or from nervousness. It is to be treated by the administration of tonics. The bladder may be affected with paralysis, resulting either from accident, from disease of the nervous centres, or from overdistention. It gives rise to incontinence of urine, which, however, is to be distinguished from that which sometimes arises from irritability, inasmuch as in this case the bladder is full, and has no power to evacuate; so that it must be drawn off by the catheter. Retention of urine may be caused by mechanical obstacles to its exit, by paralysis, or by a want of power over the

BLADDERLOCKS. (See ALARIA.)

BLADDER SENNA. (See COLUMA.)
BLADE, blaid (Ang. Sax.), the cutting part of an instrument, distinct from the handle; as the blade of a
sword, a knife, or scythe. Damascus was farmous for the manufacture of sword-blades, which are even now

ane manusceure of sword-blades, which are even now, in consequence of their celebrity, of great value.

Blade, in Bot., a term generally applied to the expanded portion of a leaf. It is the part which is assally the most highly developed, and which is popularly known as the leaf. The terms lamina and leaf are also armiled to this new! (See Terms lamina) mb are also applied to this part. (See LEAR.)

BLANCHIMETER, bldm-shim'-s-ter (Fr. blancheach.)

BLANCHIMETER, blimeshim'ester (Fr. blanchir, to blanch: Gr. metron, a measure), an instrument used in ascertaining the bleaching powers of chloride of lime

## Blank Verse

plates with a thin cost of tin is also called blanch in ecokery, the term is applied to the peaking whitening of almonds, &c.

Minerally, a process adopted by gardeners for the purpose of keeping portions of the leaf or leaf-stall; a plant protected from the action of light. Under the of or loof stalls of a plant protected from the action of light. Under influence of the sun's rays, the leaves of plants decipose carbonic acid, the carbon of which goes to fi many of the substances which give them their im-vidual character. Amongst other things, wood-lib cannot be formed without the action of light. Wh light is excluded from plants, they remain almost white and lose nearly all their coarseness and bitterness, a and lose nearly all their coarseness and hitterness, as in the cases of seakale and celery. The inner leaves of the cabbage are naturally blanched; and the leaves of lettree are often tied together in order to blanch the interior. Celery is blanched by drawing the easth up to the plant, as it grows, in trenches; and seaked is blanched by covering the leaves with boxes or puts surrounded with straw, &c. Celery, seakels, and chambarb are sometimes blanched by growing them at the bottom of coal-mines. Although simple and easy, blanching is a very important branch of gradening, as blanching is a very important branch of gardening, as many plants depend upon it for their usefulness. Blanchings, or Blanchinger, the mony [Fz.

BLANK CARTEDGE, blink, a charge of powder for a rifle or other gun, containing no ball or shot. It is usually used for firing salutes and in exercising troops.

(See CANTRIDGE.)

BLANKET, blan'-ket (Fr. blancket, the blanket of a printing-press), a soft, loosely-woven woollen staff. ncipally used for bed-coverings and wrappers. addition to those sold in the United Kingdom, five or six million yards are annually exported to other constries. The manufacture of blankets is carried on principally at Dewsbury, Wakefield, and Witney. (See WOOLLEN MANUFACTURE.) Among printers, the term is applied to a woollen cloth or fine baize, which is laid between the tympans of a press. To toss in as blanket, by way of punishment, is a very ancient custom. The emperor Otho used to go forth upon dark nights, and if he found a drunken man, he went order the discipline of the blanket to be administered.

BLANK VERSE, is verse without rhyme, — verse where, according to Dr. Johnson, "the rhyme is blanched or missed." The verse of the Greeks and Romans,—at least all of it that has come down to us, is without rhyme. The Goths are said to have introis without rhyme. The Goths are said to have introduced rhyme from the East into the languages of modern Europe, and in the Middle Ages it came to be commonly employed in poetical composition, both is the Latin and vernacular tongues, by most of the nations of Europe. About the 15th century, when the passion for imitating classical models became general, attempts were made in Italy, France, and other countries, to reject rhyme as a barbarous innovation. The first attempt at blank verse in English appears to issue been a translation of the first and fourth books of the English up the carl of Surrey, who was executed in Æneid by the earl of Surrey, who was executed in 1547. Its suitability for the drama was at once felt. and it was in general use in dramatic composition before Shakspeare began to write, which is supposed to have been about 1591. It was, however, almost esto mee been about 1991. It was, newest, analysis tirely confined to the drama down to the appearance of "Paradise Lost," by Milton, in 1667. In an adventisement to the second edition of this work, the author, in answering objections to the want of thyme, says:
"This neglect of rhyme is so little to be taken for a ascertaining the protesh.

Blancairs, blanch'-ing, a term applied to the proease of whitening anything. In coinage, the operation set the first in English, of amient liberty recovered to the first in English, of amient liberty recovered to heroic poem from the troublesome and moders beam sleaning the money.

The process of covering iron age of rhyming." Since Milton's time, blank verse has also and the contract of the contra

# Blops

come into use in various kinds of poetry besides the drematic; but it is principally in the heroic metre of ten syllables that blank werse is used, and, indeed, by some the term is restricted to that kind of metre. As an example of blank verse:—

Of man's | first dis | obe | dience, and | the fruit Of that | forbid | den tree | whose mor | tal taste Brought sin | into | the world, | and all | our woe.

Frequently, in dramatic blank verse, a supernumerary syllable occurs at the end of the line; as,—

To be, I or not | to be, | that is | the ques | tion.

In blank verse, the poet is less encumbered than in any
other species of versification; and hence it is particularly adapted for subjects calling forth sublime
and noble emotions. "The constrained elegance of
this kind of versification (rhyme), and the studied
smoothness of the sounds, answering regularly to each
other at the end of the line, though they be quite consistent with gentle emotions, yet weaken the native
force of sublimity; besides that, the superfluous words
which the poet is often obliged to introduce, in order
to fill up the rhyme, tend farther to enfeeble it."—
(Blair). It is also free from the full close which rhyme
forces upon the ear at the end of each couplet, and
allows the lines to run into each other without constraint. The German language admits of the greatest
variety of blank verse, for it seems to be used in every
kind of metre.

BLAPS, bldps, in Ent., the typical genus of the fam. Blapsida, of that ord, of insects named Colerators. Blapsida, of that ord, of insects named Colerators. Blaps mortisaga, its common one the Churchvard Beetle. It is of moderate size, sometimes of a dark, but more frequently of a black colour, and is generally to be found in murky, damp situations, or the dirty parts of dwelling-houses. Mr. Westwood makes the following extraordinary statement with regard to these insects:—"Several instances have been noticed in which the larve have been discharged from the stomach. Of these the most remarkable account is that published by Dr. Pickells in the Transactions of the Associated Physicians in Ireland, of a case of a woman, aged 28, who emitted as many as two thousand larve of this insect at various times, as well as one pupa and one omago; and which probably originated in an absurd and superstitious practice which she had for some time followed, of drinking daily, for a certain time, a quantity of water mixed with clay taken from the graves of two Catholic priests, and eating large pieces of chalk. One of these beetles was immersed repeatedly into spirits of wine, but revived after remaining therein all night, and afterwards lived three years." Tabricius states that the women in Egypt eat the Blaps sulcata cooked with butter, in order to attain that corpulent condition of body so highly esteemed as an element of female beauty by the orientals.

BLASPHIAN, blus-fe-me (Gr. blasphemia, from blapto, I hurt, and pheme, reputation), literally means defamation or evil-speaking, and at first was weed to denote simply the blaming or condemning of a person or thing. Afterwards, however, it came to be restricted to an indignity offered to the Deity, either by words or writing. Hence Augustine says,—"Jan vulgo blasphemia non accipitur, nisi mala verba de Deo discree." In the early Christian church blasphemy was regarded as of three kinds,—1. The blasphemy of apostates, whom the heathen persocutors obliged not only to deny, but to curse Christ; 2. the blasphemy of heretics and other profan- Christians; and 3. the blasphemers were "ich as, after making a profession of Christianity, turned apostates, and blasphemed Jesus Christ; this being the usual test administered to them by their persecutors. The second were such as cade a profession of Christianity, but yet, either by impious doctrines or profane discourses, decogried from the majesty and honour of God and his not religion.—For the third kind of blasphemy, that against the Holy Ghost, see subsequent article. Undersubstantial law, blasphemy was punished with the state in the law of many civilized

## Bleschemy

countries. By the canon law, biasphemy was punished only by a solemn penance; and subsequently the corporal punishment came to be commuted into a pecuniary fine. Blasphemy is usually defined to be an injury offered to God, by denying that which is due and belonging to him, or attributing to him what is not agreeable to his nature. According to Angelus ascribed to God which is not suitable to his nature, alled by divines as in content missionities. It when called by divines a sin contra misericordiam; & whe some attribute essential to his Godbead is denied,contra justitium; and 3. when that which is only proper contra justicium; and 3, when that which is day proper to the Divine Creator is attributed to the creature;—a sin contra majestatem Dei. "Three things," says one, "are essential to this crime,—1. God must be the object; 2, the words spoken or written, independently of consequences which others may derive from them, must be injurious in their nature; and 3. he who com-mits the crime must do it knowingly." According to Blackstone, the offence of "blaspheming against the Aluighty, by denying his being or providence, or by contumelious reproaches of our Saviour Jesus Christ, is punishable at common law by fine and imprisonment, or other infamous corporal punishment; for Christianity is part of the laws of England." The first The first statutory enactment against blusphemy is 9 & 10 Will.

III. c. 32, entitled, "An Act for the more effectually suppressing of blasphemy and profaneness." It states suppressing of blasphemy and profineness." It states that "many persons have of late years openly avowed and published many blasphemous and infamous opinions, contrary to the doctrines and principles of the Christian religion, greatly tending to the dishonour of Almighty God, and may prove destructive to the peace and welfare of this kingdom;" and enacts that any person or persons having been educated in, or having rade a profession of the Christian religion within the person or persons having been educated in, or having made a profession of the Christian religion within this realm, "shall by writing, printing, teaching, or advised speaking, deny any one of the persons of the Holy Trinity to be God, or shall assert or maintain that there are more gods than one, or shall deny the Christian religion to be true, or the Holy Scriptures of the Old and New Testament to be of divine authority," shall for the Gerte of the shall deny the authority," shall, for the first offence, be adjudged incapable of holding any office or employment, ecclesiastical, civil, or military; and, on a second convic-tion, shall be disabled to sue, prosecute, plead, or use any action in any court of law or equity, and shall also suffer imprisonment for three years. The main provisions of this act remain still in force; but by 53 Geo. III. c. 160, those who deny the doctrine of the Trinity are exempted from its penalties. In 1841 the law against blasphen, was enforced upon Mr. Moxon for publishing an edition of Shellev's "Queen Mab;" but the sentence was merely nominal. In Scotland, blasphemy was, by acts of the Scotlish parliament passed in 1061 and 1695, punishable by death; and the last who suffered capital punishment for this crime in Scotland was Thomas Aikenhead, a student of divinity, who was executed 1696. These severe statutes were who was executed 1896. These severe statutes were, however, repealed by 53 Geo. III. c. 160, which made the punishment arbitrary. By act 6 Geo. IV. c. 47, the publication of blasphemy was punishable by fine and imprisonment, and by banishment for a second offence; but this last was repealed by 7 Will. IV. c. 5. which rendered the punishment only fine and imprisonwhich renewed the punishment only the and imprison-ment. In 1843 a person was tried before the High Court of Justiciary at Edinburgh, for publishing books deny-ing the truth and authority of the Holy Scriptures, and tending to bring contempt upon the Christian religion, and, being found guilty, was sentenced to fifteen months' imprisonment,

BLASTHEMY AGAINST THE HOLY GHOST.—Divines are very much divided in opinion as to what the nature of this sin was. Christ says, in Matthew xii. 3t (and to the same effect in Mark iv. 20 and Luke xii. 10), "All manner of sin and blasphemy shall be forgiven unto men; but the blasphemy against the Hely Ghost shall not be forgiven unto men." In the early church some applied it to the sin of lapsing into idolatry; others to a denial of the proper Godhead of Christ; others to a denial of the divinity of the Holy Ghost Augustine resolves it into obstinacy in opposing the methods of divine grace, and continuing in this observer, did the Church reckon to be beyond the power of

#### Blast-Furnace

forgiveness; for they did not refuse to receive into their body any one who professed repentance for his sins. The general opinion now is, that it consisted in the imputing of the miracles wrought by the Holy Spleit to the power of the devil, and that it was directed against the Jews. The saying of Christ was directly called forth by the Pharisees having said, "This fallow doth not cast out devils but by Beelzebub, the prince of the devils;" and was specially addressed to them.

BLAST-FURNACE. blast' fur-maics (Sar. blast blast.

BLAST-FURNACE, blast' fur-maice (Sar. blast; blast; Fr. fournaise, furnace), a furnace used in metallurgical operations, in which the combustion of the fuel is increased to an enormous extent by a blast blown from a bellows, or by means of fans. A smith's forge Blast-furnaces is a blast-furnace on a small scale. is a blast-furnace on a small scale. Blast-furnaces are used principally for smelting iron-ores, and consist essentially of a long narrow funnel inverted upon another shorter funnel, the whole being built of solid masonry. They are usually 50 feet high by 15 feet in diameter at the largest part. At the bottom of the lower cone is a sylindrical hole, from which lead the lower cone is a cylindrical hole, from which lead the tugbies, or blast-pipes, and the channel for the passage of the melted slag, which rises on the top of the metal and overflows. At the lowest part is the tap-hole for drawing off the melted metal. At the top is a gallery for the conveyance of fuel and ore. The blast-furnace being lighted with coal, the roasted ore, combined with a flux of limestone, is thrown in; upon this is thrown another layer of coal, and so on; as the fuel burns away the mass sinks, and is so on; as the fuel burns away, the mass sinks, and is replanished with fuel, flux, and ore from the top. The sunexed engravings relate to the construction of blast-furnaces, and to various improvements and modifications connected therewith. Heretofore it has been the custom, during the process of smelting iron-stone or ore, to allow the charge to remain some days in the furnace for the purpose of "cementing," as it is termed; such being understood to mean the distribu-tion of the metal over the surface of the material, so that it may receive the full force of the caloric evolved by the reverberation in the smelting-furnace. Fig. 1 represents a sectional elevation of a blast-furnace

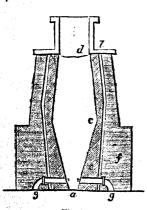

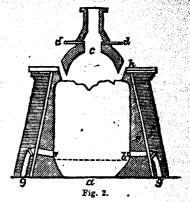

Fig. 1.

rounding the base in the figure just referred to. materials are thrown in from the top, which is open to the passage of the flame and unconsumed gases, instead of arresting their progress for the production of greater heat during the smelting process. Fig. 2 represents a modification of the above arrangements, consisting only in the dome or arched top placed just above the landing h, the object of which is to deflect downwards the rays of heat and the unconsumed gases anymorards the rays of heat and the unconsumed gases scolved; d shows two dampers for the purpose of regulating the draught, by opening or closing the crown of the dome; it are slots or apertures passing form, which is considerably less in height and greater transversely down by the sides of the landing for amplying the furnace. Fig. 3 represents a sectional of tuyeres, as well as offering facilities for feeding the

#### Blast-Furnace

elevation of a blast furnace of the improved constitution, the form of which being greatly diminished in height, the operation of raising up the materials for

forming the products is rendered less troublesome than hitherto. The mede of working and the arrangements generally are the same from the hearth upwards, with the exception of the boshes; the sides are nearly tical, with a slight curve at the shoulder or bending; the form of the dome

or cover, as before de-scribed for concentrating and retaining the heat, is of such material and construction that the effect pro-duced during the process of smelting iron-ore, or other metallic substances, causes quicker deposit of the products, enabling them to be entirely withdrawn at shorter intervals by the in-creased intensity of the heat generated. Fig. 4 shows a sectional plan view of fig. 2, taken through the dotted line

according to the old plan,

such as is now in use. The

as follows :- The

materials to be placed in the blast-furnace are directed through the chamber a, which, by the use of a conically-formed trap or bottom, are deflected off from the surface in an outward direction, and by falling on the larger one beneath, caused to descend and be de-posited round the sides of the furnace, when a greater degree of heat is given off. Fig. 6 represents a blowing apparatus, which consists of an upright framework, to the top portion of which the blowing apparatus is fixed, the other end

having a sliding bar working on the side-rods b; c is a small cylinder fixed to the bed-frame, with piston and connecting rod attached vertically to the lower portion of the blowing apparatus; d is the steam or ingress pipe; e, the blast branch-pipe communicating with the tuyeres. In putting the machine into operation, it is first necessary by suitable valves to admit the steam below the cylinder g, the effect of which upon the blowing apparatus will be to cause it to move upward, and impel the air from through the tube e

Fig. 6. into the furnace; ff are springs for bringing down the apparatus in readiness to be again raised by the steam piston. The patentee of this improved form of blast-furnace also describes an improved tuyère capable of passing into the furnace and being kept cool, without the application of water-passages through it, using for such means currents of air instead; also for combining and arranging blowing cylinders having steam-engines attached; the novelty of which consists in uniting two air-pump cylinders with inlet and outlet valves communicating with the tuyeres and working the same backwards and forwards by the up-and-down stroke of the piston, as hersetofore, the rod of which is attached to the pistons of the air-pumps, which are so constructed with buffers of india-rubber that when the piston completes each alternate stroke, it shall be prevented from the piston and of the available whereby a from striking the ends of the cylinder; whereby a pressure of air is maintained of uniform strength withont the employment of fly-wheels. The patentee also claims as a novelty his mode of employing two or more fans placed on the same shaft, and made to revolve by a rotary steam-engine in such a manner that the air or blast from the first fan shall enter into the second, and from the second fan into the third; and so on if desirable; thus accumulating a more powerful blast to be passed into the furnace than has hitherto been employed. The more important peculiarities of this invention are—the improved mode of constructing this invention are—the improved mode of constructing I mis, and as many such construction of the manner above described; the blasts to be fired, areefixed in their proper places along the conducting wire, and each is introduced the peculiar mode of arranging and combining blowing—the charging and tamping not to disturb the connections.

#### Blestine

cylinders having steam-engines attached, pressure of air is kept uniform withou ment of fly-wheels; the means of regulating bi air to blast furnaces by the presume of steam springs; finally, the application of two or more upon the same shaft when receiving motion from

shaft. (See Igon.)

BLASTING (Ang.-Sar.)—An operation in Mining
&c., by which large masses of rock are separated a
means of the explosion of gunpowder or gun-cotton A small opening is bored in the rock or stone, and A small opening is bored in the rock or stone, and is fired by means of a fuse or train. In engineering operations of large magnitude, chambers, and even galleries, are formed in the rock, bags of powder being inserted, and tired by means of the galvanic current. By this means enormous masses of rock, weighing thousands of the way are removed with the greatest case. One of of tons, are removed with the greatest ea One of the largest blasting operations known was that in which 400,000 cubic yards of cliff at Folkescone were removed at one time by the explosion of 18,000 lb. of powder, during the construction of the South-Eastern Railway. Blasting is also much used for removing submerged Blasting is also much used for removing sugmerger, wrecks: the ruising of the wreck of the Royal George, at Spithead, was effected by means of submarine blasting. The charges in this instance were fired by divers, the powder being ignited by a galvanic current. The sale of the recovered brass guns more than paid for the expenses of the operations. Submarine the same of the submarine merged rocks are removed in a similar manner, marine blasting of rocks has been successfully prose cuted, with the use of the diving bell, for sinking the holes and charging them with cartridges, contained in a tin tube. From this a smaller tube is extended to the surface, which, when filled with powder, is fired. The effect of powder fired under the pressure of the water appears to be greater than in explosions of a similar kind upon the land. The fragments are removed but a short distance, and little disturbance is caused upon the surface of the water. It has been found that ledges of rock in this situation may be found that ledges of rock in this situation may be reduced in height without boring holes, simply by exploding large charges of powder upon the surface of the rock by means of the galvanic battery. In this way the surfaces of several dangerous ledges of rock in New York harbour have been taken off, and the depth of water increased over them. In Scotland a battery has been introduced, of very compact arrangement, designed for igniting charges at a distance. It is constructed of zinc and cast-iron plates alternating with each, and about a quarter of an inch apart. The first and second it on plates are connected together as a double terminal plate, from which proceeds the wire forming the positive pole. The first zinc plate is united by a strip of metal with the third iron plate, the second zinc with the fourth iron, and so on to the end of the series, which may consist of twenty plates of zinc and twenty-one of iron. The last zinc plates of zine and twenty-one of non.

plate will be disconnected with the rest, and from this

connected with the negative pole. The proceeds the wire forming the negative pole. plates are separated by slips of wood a quarter of an inch thick, and are kept in place by two pieces of board at the ends, connected by cross strips at the poard at the ends, connected by cross strips at the sides, and with one at the bottom to prevent the plates from falling out. As two plates intervene between every pair in metallic connection, there is no occasion for partitions in the trough. The space required for a battery of twenty pairs, or of forty-one single plates, will not exceed twenty inches in length. Such a battery is readily constructed, and is found to be efficient at a distance of five hundred feet. By adding a section of the same kind, the charges may be fired at still greater distances. The conducting be fired at still greater distances. The conducting-wires of copper should be insulated by a covering of silk or cotton thread, and several inohes near their extremities be twisted together. The two ends should diverge from the twist as far as the diameter of the hole for the charge will admit, and a fine steel wire, like those used for the hair springs of watches, or a fine platinum wire, should connect the two pules. This, and as many such connections as there are

ons. A gatest has been intely taken out in this souncy or splitting rocks by the generation of heat without attaing an explosion. The inventors use a substance composed of 160 parts of sulphur by weight, 100 of subpetre, 50 of sawdust, 50 of horse masure, and 10-of common sait. The saltpetre and common sait are to which four parts of moissess of common sait. The sattpetre and common sait are dissolved in hot water, to which four parts of molasses are added, and the whole ingredients attred until they are thoroughly incorporated together in one many, which is then dried by a gentle heat in a room, or by exposure to the sun. After this it is fit for use. It is tamped in the holes bored for blasting rocks in the same manner as gunpowder, and is ignited by a fusee. It does not cause an explosion upward like gunpowder, but generates a gentle heat, which splits the rock.
The Austrian engineers prefer electricity as a blasting The Austrian signeers prefer electricity as a making agent. With the apparatus they employ, explosions have been produced at a distance of one and a half German leagues, and fifty mines exploded simultaneously on a line of a hundred fathoms. The process has been in use under water in the Danube, near Grein, and the marble quarries near Neustadt, for some years with the state of t with perfect success.

BLATTA. (See BLATTIDE.)
BLATTA BYZANTIA, in Pharmacy, is an old term for marine substance employed as a remedy for epilepsy, hysteris, &c. It is of a reddish-brown colour, pleasant odour, and shaped like a finger nail; whence it was also called *Unquis odoratus*. It was likewise used for the oblong operculum of certain shell-fish.— Ref. Mayne's Lexicon.

BLATTER, blatt-ti-de (Lat. blatta, an insect that eats away clothes), a fam. of insects belonging to the ord. Orthoptera. The insects of this family are extremely active and voracious. According to Mr. Stephens, there are only seven species indigenous to this country, among the most disagreeable of which is the well-known Cockroach, or Black-beetle. (See BLACK-BEETLE.) In hot climates, where the number of species of this family is very large, their ravages are exceedingly great. The largest of the genus is the Blatta gigantea of Linnsous, which is indigenous to the warmer parts of Asia, South America, and Africa, where "they plunder and crode all kinds of victuals, dressed and undressed, and damage all sorts of clothes, especially such as are touched with powder, pomatum, and similar substances; everything made of leather, books, paper, and various other articles, which, if they do not destroy, at least they soil, as they frequently deposit a drop of their excrement where they settle, and some way or other, by that means, damage what they cannot devour. They fly into the flame of candles, and sometimes into the dishes; are very fond of ink and of oil, into which they are apt to fall and perish; in which case they soon turn most offensively putrid; so that a man might as well sit over the cadaverous body of a large animal as write with the ink in which they have died. They often fly with the ink in which they have died. They often fly into persons' faces or besoms, and their legs being armed with sharp spines, the pricking excites a sudden horror not easily described. In old houses they awarm by myriads, making every part filthy beyond description wherever they harbour, which, in the daytine, is in dark corners, behind clothes, in trunks, boxes, and in short every place where they can lie concealed. In old timber and deal houses, when the family is retired at night to sleep, this insect, among other disagreeable properties, has the power of making a noise which very much resembles a pretty smart knocking with the knuckle upon the wainscoting. The Blatta cigantes. knuckle upon the wainscoting. The Blatta gigantea, in the West Indies, is therefore frequently known by the name of the Drummer. Three or four of these noisy creatures will sometimes be impelled to answer one another, and cause such a drumming noise, that none but those who are very good sleepers can rest for them. What is most disagreeable, those who have for them. What is most consigned and, there will have not game outstains are sometimes attacked by them in their sloop; the sick and dying have their extremities attacked, and the ends of the toes and fingers of the dead are frequently stripped both of the skin and flesh." The Blatta americana, or American cockroach, is another member of this troublesome family. size is somewhat larger than that of the black-beetle; but its destructive powers are little less. It is now becoming common in England, especially in scapora-towns, where it is brought with merchandise from 287

abroad. The Bietta lapposice is a survivide in the sound in Laplaced in gr When very numerous, instances have whose they have devoured the whole of winter provision of dried lish. Perhaps singular circumstance counteted with the consists in the manuer in which they dep Perhaps th eggs. Instead of laying her eggs singly, as most insects do, the female drops an oblong mass, which serves as a case for an emire family of young blates. From this prison Nature has provided the young insects with a means of escape at the fitting moment. This counists of a fluid which they emit, and which softens the cement of the deuticulated margins of the case, or cocoon, as it might be termed, in which they have hitherto been enclosed. The cocoon of the blatte contains about sixteen eggs, of an oblong oval form, arranged in a double series. In this protesting form, arranged in a double series. In this state of maturity ere they emerge into freedom. arranging and laying of this occoon occupy the female during a week; and so careful is she of this egg-pouch, that on leaving it she carefully covers in with the materials of the substance upon which she places it. The larves and pupes are equally active with the image, and not less destructive, differing for the most part in their smaller size.

BLAZONRY, blai'-zon-re (Sax. blæsen; Ger. blasse, to blow a horn; Fr. blasonner, to blase about, make public), the art of painting and describing armorial earings in heraldic phraseology. The term originated bearings in neutron of sounding a trumpet when a traight entered the lists at a tournament, after which the officiating heralds proclaimed his title, and the distinctive bearings on his shield, with his creat, badge, and motto. The principal rules for blasoung coatering, according to English usage, are as follows; but on the Continent they are not all observed with thirt differences. strict adherence. 1. In marshalling coats of arms it is false heraldry to place metal upon metal, or colour upon colour. 2. Begin with menticaing the metal or colour of which the field is composed, steing the direction of the lines by which it may happen to be divided; as, per bend, per fess, quarterly, &c., and if they assume other forms than the simple straight lines (see Engralled, Wavy, Raguly, &c.), and then proceed to the principal and secondary charges in order. 3. Shorten the description as much as possible, and avoid all repetition of the names of metals and colours, mentioning a charge of any colours. strict adherence. 1. In marshalling coats-of-arms it and colours, mentioning a charge of any colour or metal that has been named before, as of the first, of the second, &c. Thus, the cont-of-arms in the accom-

panying engraving would be described as Argent, on a bend engrailed gules, between two hurts, a mullet or, pierced of the second between two crescents of the first: in which then the principal charges on the field; and thirdly, the charges on the ordinary, in their proper metals and tinc-tures, without repetition. 4. tures, In describing charges in a

field or on an ordinary, between others of a different nature, always name that charge first which is nearest to the centre of the shield. Thus, in the above example, it is correct to say a mullet between two crescents, not two crescents with a mullet between them. 5. When saimals, plants, &c., are represented in their natural colours, they must be always de-scribed as proper only, without naming any metal or colour; thus we must say a swan proper, not a swan

colour; thus we make the colour; thus we make the colour of the colour o actinism), air, and moisture; and it occupied than months to effect what modern chemistry enables us to perform in a lew hours. The process of bleaching lines

# Bleaching-Powder

is very ancient, perticularly in Egypt, where white lines was greatly prized. Frections to the middle of the last century, the method of bleaching was unknown in Eugland; and the lines manufacturers of the North sent their fabrics to Holland to be bleached, whence they received them in eight or nine months. The Dutch method of procedure bonsisted in soaking the lines for several days in potach lye, which was used whilst bolding. The lines was then washed, and put into tube containing buttermilk, for several days. It was afterwards spread on the grass for some months, being continually sprinkled with water during this time. The linen was returned to England in a nearly white condition, and went by the name of brown Holland, a name still preserved by a partially bleached lines fabric. The first improvement in this tedious process was made by Dr. Home, of Edinburgh, who, by substituting weak sulphuric acid for the buttermilk, succeeded in reducing the time required to six or neven weeks. In 1787, however, a most important change was made by the discovery of Berthollet that the gas chlorine obtained by the action of hydrochloric the gas chlorine obtained by the action of hydrochloric acid on binoxide of manganese formed a very perfect bleaching agent. Chlorine was first used in solution; but it was not found to answer the purpose in this bondition. In 1798, Mr. Tennant, of Glaspow, took out a patent for impregnating dry hydrate of lime with chlorine gas, forming what is known as chloride of lime, or bleaching-powder. (See Rikaching-Powder.) The bleaching-powder of England and Scotlend are or bleaching-powder. (See RLEACHING-POWDER.)
The bleaching-works of England and Scotland are on
a par with the demand for their use caused by the enormous amount of calico and other cotton fabrics now manufactured in this country; and it is not too much to say, that the supremacy enjoyed by England as the great cotton-fabric producing country is due almost as much to the perfection with which bleaching amost as much to the perfection with which beaching is carried on, as to any other cause. The process of bleaching is briefly as follows:—Pieces of cotton cloth, or calico, are sewn together into a continuous web seven or eight miles long. This, being united at the ends, forms an endless band, which passes over rollers, like the endless band of a lathe. It is first drawn over a the the endless Dang of a nature. At a mount of the house fibres: it is then washed, to remove the dressing, and afterwards passed through a hot solution of lime. It is once more washed, to remove the lime, and then run through a weak colution of sulphuric acid. It is washed a third a weak solution of sulphuric acid. It is washed a third time, boiled in a solution of sode, washed again, and rinsad in a weak solution of bleaching-powder. It then lies for some time in a heap, to allow the chlorine to act; after which it is again dipped in acid, washed, steeped in soda, washed again, dipped in bleaching solution, dipped in acid once more, washed for the last time, dried, and folded, after naving been rived once more into pieces. The perfection of the ripped once more into pieces. The perfection of the machinery and method of working the chemical part of bleaching must be very great when a piece of calico 28 yards long undergoes so many complicated processes for sixpence! In 1803 the charge for the same amount of work was 7s. 6d. Hardly a week passes without some improvement in bleaching taking place, and the list of patents is full of contrivances of all kinds for atill further cheapening this important manufacturing process. The consequence of this activity is, that more fabrics are bleached in a few hours in a space a few feet square, than were bleached formerly in many months and spread over many acres of ground. The colouring matter of fibres seems to be a kind of resin, which is dissolved partly by means of the alkali used, and partly by the chlorine and dilute sulphuric acid Silk, straw, feathers, ginger, and certain spices, are generally bleached by means of sulphurous acid. Wax, however, is bleached by the combined action of light,

BLEACHING-Powner.—Of all bleaching compounds, chloride of lime is the most important. It is prepared by exposing slaked lime to the action of chlorine gas. Slaked lime may be made to combine with half its weight of oblorine. Chemists are divided as to the true composition of this valuable compound, some looking on it as a hypochlorite of lime, CaO.ClO, united with chloride of calcium, CaCl, while others regard it as a combination of chlorine with oxide of calcium, in the form of an oxychloride, CaOCl. Chloride, it is a combination of chlorine with oxide of calcium, in the form of an oxychloride, CaOCl. Chloride.

#### Blanning

off hypochlorous acid. Its principal use is as a bleaching agent; but it is also employed as a disinfectant with great success. (See Linn, Chicampa or.)

Biran, bleek (Leucieus alburnus), a little allyaryscaled fish, well known to British anglers. It is said
that the scales of the bleak are used in the manufacture

of imitation pearls.

BLEEDING, C. BLOOD-LETTING, Weed' ing (Sax. Medica; to bleed), in Surg., is the removing of blood from the body, with a view to the prevention or cure of disease. It is divided into general and local: venesection and arteriotomy are instances of the former; scarification, of the local control of the lo cupping, and the application of leeches, of the latter. General bleeding is had recourse to when the object is to lessen the whole mass of the circulating fluid ; local, when the object is to lessen the quantity in some par-ticular part of the body. Venesection is the mode usually had recourse to in general bleeding, and the veins most commonly selected for the purpose such those at the bend of the elbow. In proceeding to open a vein, a bandage is first placed moderately tight round the arm, above the elbow, to obstruct the return of the venous blood; and when the veins begin to swell, the operator selects one, and pressing the thumb swell, the operator selects one, and pressing are caumo of his left hand upon it, at a short distance below the spot where the opening is to be made, presses the lancet into the vein, and gives a slight cut upward in withdrawing it, so as to make the opening sufficiently large to allow the blood to flow out in a thin stream. When a sufficient quantity of blood has been abstracted, the operator's thumb should be placed on the cut in the vein and the bandage removed, when a folded piece of lint, placed over the wound and secured by a figure of 8 bandage, will be sufficient to prevent the bleeding, and the wound will speedily heal. It should be borne in mind, however, that bleeding is always a dangerous operation, even apart from the evils that may be produced from the abstraction of too much blood, and should never be performed, except in very urgent cases, by any but a skilful surgeon. For local bleeding, leeches are always the safest, and are most generally had recourse to. In dealing with leeches, it is well to remember that they are cold-blooded animals, and that heat is highly injurious to them, and undits them for the performance of their office. Hence, when there is a difficulty in making them fix readily, the part should be cooled with a cloth dipped in cold water, or moistened with cream or milk, or a single drop of porter, and the lecches confined in the proper situation under a small glass. In former times, bleedattuation under a small glass. In former times, bleed-ing was much more practised than it is at present. It was resorted to in almost every disease, particularly such as were inflammatory, or were thought to be so; and even where no disease existed, it was regarded as an excellent precautionary measure to have a v opened once or twice a year. Some contend that this mode of proceeding was then necessary, and that, since that time, a great change has taken place in the physical constitution of the people. Doubtless, there is some truth in this; but we cannot believe that the constitution of the people ever was such as to justify the wholesale bleeding that was at one time practised. For bleeding, or a flow of blood from any of the organs, see HEMORRHAGE.

BLENDR, blend (Ger. blenden, to dazzle), a term applied to several minerals possessed of a peculiar glittering lustre, such as hornblende, bismuth-blende, &c. The term, by itself, is generally applied to zinc-blende, or sulphide of zinc.

BLENNIEM SPANIEL. (See SPANIEL.)
BLENNIUS, blen'-ni-us (Gr. blenna, mucus), a gen of fishes belonging to the section Acanthopterygii and

ride of lime is a white, moist powder, continually giving pally recognizable from their having the ventral an

## Blennorrhees

placed before the pectoral. They congregate in small shouls upon rocky coasts, where upon the reflux of the tide, they may be often found in pools among the crevices of the rocks. Mr. Yarreli rates that five apecies frequent the English coasts. These are,—Montagu's, or the Diminutive Blenny; the Occluded Elenny, or Butterfly-fish; the Gattoruginous Blenny; the Shanny; and the Crested, or Yarrell's Blenny;

RELENSCRETCA, blen-nor-re'-a (Gr. blenna, mucus; ries, I flow), is a term used in medicine to denote an unusual discharge of mucus from any of the mucous mambranes.

BLESDOR, bles'-bok (Gazella allifrons), a fleet auto-lope of Southern Africa.

BLESDOR, blife (Sax. belihtan, to fall upon), a gene-ral term for a certain class of diseases which affect the cultivated grasses, especially the cerealia. It is generally limited to the disease to which wheat and other rilly limited to the disease to which wheat and other grains are liable, when the outside of the plant remains green and flourishing while the interior is filled with a powder having a very festid amell. This powder consists of a microscopical fungus in the shape of balls, so minute that four millions of them may be present in a grain. This disease is also called smut-balls, bunt, pepper-brand, and stinking rust. The name of blight has been applied to every kind of disease incidental has been applied to every kind of disease incidental to plants through changes in the state of the atmo-sphere, the condition of the soil, ravages of insects, parasitic fungi, &c. The name has also been given to diseases of plants which have arisen through errors in cuseases or plants which have arisen through errors in cultivation. Insects and parasitic fungi attack un-healthy plants first; and often when the evil has been ascribed to them, the true cause has been some mis-take in manuring the soil. A competent authority on the subject observes, "There is a kind of blight sometimes very prevalent, which has been referred to fungi, but which is, in fact, nothing more than an excessive development of the epidermal cells, which are no longer kept within bounds by the real cuticle," but become "elongated, and frequently branched in various ways, so as to form spongy or mealy patches, which are sometimes in such abundance as from their bright colour or peculiar aspect to attract general notice."
This species of blight does little damage to the plant on which it is found, and is most commonly ob-served on woody plants, such as vines and hawthorn. A similar effect sometimes appears on a few herbaceous

BLIND, blind (Aug. Sax.), a screen or shade at-tacked to either the inside or the outside of a window, as a protection against the sun. The most common form of inside window-blind consists of a plain hanging of union holland or linen. The wire-blind, another kind of inside window-blind, consists of a frame of woven wire-gauze, or of perforated zinc, and is fre-quently painted, and sometimes also lettered and figured. Outside window-blinds are called Florentine, Venetian, Spanish, and shutter-blinds. There are also other blinds for shop-fronts, skylights, &c., known by various

Spanish, and shutter-blinds. There are also other blinds for shop-fronts, skylights, &c., known by various names; as, common roller, spring-patent, &c.

BLUM, is a term applied to one who is deprived of the use of sight. There is none of the senses that affords such as endless variety of perceptions, such a fund of materials for the mind,—the imagination, to work upon, as that of sight. When one considers the infinitely greater amount of information that is received by the eye than by the ear, he is naturally led to the conclusion that the blind must be in a much more helpless and pitiable condition than the deaf. In reality, however, this is found not to be the case; and various attempts have been made to account for it. The blind, as a class, are lively and cheerful; the deaf, shy and melancholy, often morose and suspicious. "Take," says Dr. Watson, "a boy, it may be, of 9 or 10 years of age, who has never seen the light, and you will find him conversible, and ready to give long parratives of past occurrences, &c. Place by his side a boy of the same age who has had the misforture to be born deaf, and observe the contrast. The latter is insensible to all you say; he smiles, perspectively in the same of holy light; he enjoys the face of nature, nay, reads with attention your features, and, by sympathy, sensets your smile or frown. But he remains mute;

## Blind

he gives no account of past experience or of future hope. You attempt to draw something of this sor from him; he tries to understand, and to make him from him; he tries to understand, and to make him-self understood; but he cannot. He beassmes emban-rassed; you feel for him, and turn away from a seeme too trying, under the impression that; of these two children of misfortane, the comparison is greatly in favour of the blind, who appears by his language to enter into all your feelings and conceptions, while the unfortunate deaf-mute can hardly be regarded as a rational being; yet he pessesses all the advantages of visual information as direct sensation." The cause is not that the blind possess a greater, or snything like visual information as direct sensation." The cause is not that the blind possess a greater, or snything like an equal, stock of materials for mental operations, but that "they possess an invaluable engine for forwarding these operations, however scarty the materials to operate upon,—artificial language," which is the medium of thinking; and "its value to a man is nearly equivalent to that of his reasoning faculties." The truth is, that the deaf are far more isolated all their lives from these that hear that he his interesting the same of th that the deal are lar more tsolated all their lives from those that hear than the blind are from those that can offer our interest in each other," says Dr. Wilson, "far exceeds, and ought to exceed, our interest in the world; and from all this human sympathy the deaf are almost totally cut off; while the blind, excused from many duties which the seeing can only discharge, are peculiarly free to indulge in gossip with their more peculiarly free to indulige in gossip with their micro-favoured neighbours, and can largely exchange opti-nions with them. Moreover, the blind can sourcely fail to find their own tastes suited in some portions of the talk of their neighbours; "" whilst the deaf, unless they have a great aptitude for such occupations as employ the eye and the hand, are far more narrowed in their circle of studies, and much more solitary th in their circle of studies, and much more solitary than the blind." There have been blind travellers, like Holman; blind poets, like Homer, Milton, and Black-lock; blind divines, like Lucas and Troughton; blind mathematicians, like Saunderson and Moyes; blind naturalists, like Huber; blind historians, like Prescott; blind musicians, blind sculptors, blind mechanicians; indeed, Dr. Reid asserts that "sight discovers almost nothing which the blind may not comprehend." But their concentions of many thines must, at least But their conceptions of many things must, at least, be very imperfect; light, colour, and space, must ever be words which they cannot fully realize. The blind are able to make up, in great measure, for their want of sight by the greater development of their other senses. By assiduous application and attention, the senses of touch and hearing become much more deli-oate and acute. It has even been said that some have been able to distinguish colours by means of touch; but this seems very doubtful. By accurately distinguishing the various kinds and modifications of sound, they are the various kinds and modifications of sound, they are able to form correct ideas on many subjects. Much, too, depends upon the memory, which, from exercise, becomes much more retentive than in ordinary cases. "It is a remarkable fact," says Mr. Anderson, who has had large experience among the blind, "that they scarcely ever hurt themselves, either against furniture or in play. At Edinburgh, they were constantly walking about the crowded streets. There were four or five messequers whose business it was to carry home. about the crowded streets. There were four or five messengers, whose business it was to carry home all messengers, whose dusiness it was to carry nome am the goods sold,—baskets, mattresses, rope-mats; and not only did they do this with the greatest existiness, but they were daily in the habit of going to all parts of the city,—Leith, Portobello, and environs, to take measurements for bedding. I have many times had the dimensions of two and even three beds brought to me, all on memory, with a precision not exceeded by the most expert workman, including the exact allowance of so many inches to be cut out for the bedposts."—(Ref. Observations on the Employment, Education, and Habits of the Edind, by T. Anderson: The Lost Sames, by Dr. John Kitto; The Five Gaterays of Kassingle, by Dr. George Wilson.) It is estimated that there are no fewer than 3,000,000 of blind persons in the world at the present time. Of this vast number, 37,000 are in France, about 45,000 in Germany, upwards of 70,000 in Russia, about 3,000 in Holland, 6,700 in Sweden, upwards of 2,000 in Norwsy, and about 29,000 in the British isless. According to the census of 1851, there were, in Great Britain and the islands, of the British seas (exclusive of Ireland), 21,487 (11,27) and 10,214 females) persons totally blind. In proporation to the population, there was 1 blind person in so many inches to be cut out for the bedposts."

escry 675 in Greek Britsen; I in 675 in England and Wales; I in 661 in Gentlin Geolius, In Ireland there was I blind for seary 855 period. As compared with other countries, it is frome that in the level portions of Europa, comprising Belgium, Hanovar, parts of Generally, and the plains of Lombardy and Denmark, the average is nearly the same as that of Great Britain, being I in every 650 inhabitants. In more elevated against she preportion is considerably lower, except that in fluxway it is as high as I in every 462 inhabitants. The number of blind persons in early life is not large. Of the 21,487 blind persons in Great Britain, only 1500, or less than 14 per cent., were under 14 years of age (a preumstance tending to show that cases I blindness at birth are not very common); between 18 and 60 years of age, there were 8,466 persons, or about 39 per cent; while 10,102 persons, or 47 per sent, were above 60 years of age; showing that in many same the employments followed in pepulous manufacturing towns, and that crowded dwellings and other recognitions, by inducing diseases of the organs of sight, have caused a greater amount of blindness in towns than in rural localities. It is clear, however, from the census returns, that a much larger proportion of blind persons exist in the agricultural than in the manufacturing and mining counties. For example, in Wilts, Dorset, Devon, Cornwall, and Somerset, there was a naverage of 1 blind in every 758 inhabitants; whereas in the West Ridding of Yorkshire, there was I in every 1,231; in Leoda, the proportion of blind is 1 in every 1,231; in Life, and in Staffordshire, 1 in 1,602. This may partly arise from the greater proportion of blind in the arrivaltural districts; but it is also to be borne in mind that the blinds are located in our principal cities and towns. In London, the proportion of blind in the rural districts is owing in some measure to the constant expense of the eye to the sun and the inclemencies of the wester proportion of blind in the rural districts is owin

BLEET, EDUCATION OF THE.—It was not till towards the close of the last century that any effort was made for the education of the blind. The first school established for that purpose was that of Paris, founded in 1724. It was followed by those of Liverpool, Edinburgh, and London, established in 1790, 1791, and 1800, impositively. Since that time schools have been established in most of the large cities and towns of the kingdom. One great obstacle in the way of the education of the blind, are the numerous systems that at present are in use for teaching them to read. M. Haily was the inventor of the art of printing in relief; but various attempts had been made before his time to give them a knowledge of letters. The French system of M. Haily was subsequently much improved upon by Mr. James Gall, of Edinburgh, who employed only one alphabet in place of two (capital and small letters), and excluded curves and circles, substituting angles and straight lines. He published several preparatory books in this style for the use of the blind. A few years later, in 1832, the Society of Arts in Scotland offered their gold medal for the best arbitates and method of printing for the use of the blind, which was awarded to Dr. Fry. Mr. Alston, of the substray. The arphabetical comprise,—I. Means the properties—I liston's system of Roman capitals; 2. the American system of smaller capitals, with serreted odges; 3. the Prench Sphabetical; and A Alston's modified. The Printed Sphabetical; and A second of the substray are and alsocates and alsocates. Each of these system has its advocates and alsocates. Acades are printed in them; and, as few listing of the saystem has its advocates and alsocates. Each of these system has its advocates and alsocates. Acades are printed in them; and, as few listing of the property of the system are unintelligible to them. Mr. E. C. Johnson, in his "Tangible Typo-

graphy," thus lays down the conditions to be ratiolal in any system comployed in the baseding of the trind: "The system of emboused printing for their me show embrace at least the following features: It must somble as nearly as possible the type in ordinary or among those who have eventual; (a) that the bits scholar learning to read may have eventy possible be from words which have have eventy good to be from words which have been must described. (b) that have have been to the from the finger must described. from words which he hay have sometry sees which now his fingers must decipher; '60 that he derive help in learning from any one who can reordinary book, or, if needful, that his friend may be to read to him. 2. It must present the words som spelt in full, that, when he learns to write, he may in a correct manner, which others can read. I which the finger hardened by long work and the touch of the little child may be able aiths to discer. The system of Mr. Alston is that which seems to m with most favour, as being that which is most e learned and most nearly allied to ordinary letters. has simply adopted the ordinary Roman letters in such a form as to be most easily felt. The Americaus adopt Alston's system, but with a smaller type, which ren-ders their books more difficult to read, though it leasens the cost of them. In what are called the arbitrary systems, in place of the ordinary letters of the alphabet, arbitrary characters are adopted. One of the principal of these is the system of Mr. M. T. Lucas, which professes to be to a blind person what atenography is to a seeing person. His alphabet is composed of thirty-six obsracters, ten of which represent double letters. Not only are all letters omitted that are not necessary to the sound, but in many cases single letters stand for words; as f for the; y, yet; w, me; b, by, &c. The advantage claimed for the system is the saving of trues, nears, nears, and labour; in the printing lessens the cost of them. In what are called me; b, by, &c. The advantage claimed for this system is the saving of types, paper, and labour in the printing of books; but this is found not to be the case, for the characters occupy more space than if the words were all written at full length in Roman capitals; while it must be much more difficult to master, and must give rise to frequent confusion. The New Testament in Alston's system is comprised within 623 pages; whereas in Lucas's it occupies 841. The system of Frere is also Lucas 8 R Occupies out. The system of Front as many stenographic, founded on Gurney's shorthand, as that of Lucas was on Byrom's. Its distinctive feature, as compared with Lucas's, is that it is phonetic, the characters being intended to represent the simple sounds of the English language, rather than the letters; and each word is represented according to its promusand each word is represented according to its primary criation. The alphabet is composed of thirty-two characters, to each of which is attached a short description intended to fix more strongly in the memory of the learner the force of the character. The vowels are represented by simple dots, which, in different positions, represent the different vowels, and are divided into five long and five short. There are also twelve rules in verse for teaching the learner how to supply the omitted vowels correctly. Mr. Moon's to supply the omitted vowels correctly. Mr. Moon's system is certainly the best of the arbitrary systems. His alphabet consists of "the common letters simplified;" in other words, six of the Roman letters re-main unaltered; twelve others have parts left out, so as to be open to the touch; the rest are new and simple forms. It will be found, however, on examination, that the resemblance between Mr. Moon's letters and the Roman capitals is by no means so great as one might expect from his statement. "A letter," he says, "must consist of only one or two fines, to be felt by the thick finger of an adult." The words are all spelt at full length. Mr. Moon's system it, however, the most cambrous and expensive that has got been devised,—circumstances which are much again popularity. An ingenious "string alphabet," enabling the blind to read and write or correenabling the blind to read and write or correspond with each other, was invented some time ago by David Macheath and Robert Milne, two immetes of the Edinburgh Asylum, and has been found to answer its purpose remarkshy well. The different leaders of the alphabet are represented by different kinds and combinations of knots on a cord. They are distributed into seven classes, each class comprehending four letters, except the last, which has only two. The first, or A class, is distinguished by a large round knot; the second, or B class, by a lenst projecting from the line; the third, or I class, by a next of

da common knot orth, by the pharacteristic and a e mode of teaching rch from ised music is now little pracmount of re ing found, from their great strength of they are able to learn very long piece means of the ear alone. Embossed maps and bet are employed for teaching them geography; in addition to raised maps of the heavens, various remista, contrivances have been resorted to for g them acquainted with different branches of removing the knowledge. They are instructed in things by means of a board containing a series of atagonal holes, which receive pentagonal pins, representing the ten digits. By the use of such boards, they may be carried to any extent in arithmetical knowledge. They may be taught mathematics by means of a board full of small holes, with a few pina fitted to them, so as to represent certain letters; while, with a cord extended from the different points, tre formed the lines of the figure or diagram. stocess of Saunderson, Moyes, and others, sufficiently proves that blindness is no great impediment to a know-ledge of mathematics; indeed, according to some, the billind possess great advantages. In the various educad possess great advantages. In the various educa-al establishments for the blind, they are instructed in snady manual occupations, as in the making of basksts, mats, rugs, shoes, and such-like; for, in the words of Dr. Lettsom, "He who enables a blind person, without any excess of labour, to earn his own fivelehood, does him more real service than if he had pensioned him for life." For an account of the principal educational establishments for the blind throughout the country, see Knight's English Cyclo-patie—Arts and Sciences.

BEIFFACE, blind'-oj (Sax. blind), in Mil., any apporary construction to secure soldiers from the fire or the observation of an enemy. It consists prinand the operation of an energy.

The maily of beams of timber, against which fascines are said, which are covered with earth, turf, and raw less. When a fort is besieged, and it happens to be hides. ithout casemates for the protection of the soldiers, covered sheds of this kind are sometimes made, which erre them for a retreat, and a secure place in which they may lodge their provisions and ammunition. These are generally built by placing beams at an angle of 450 at short intervals from each other, against any of all as short intervals from each other, against any wall fit for the purpose, or the revertment of the coun-terseary, and covering them with fascines and earth. Semastines blindages are made by putting timbers against each other like the roof of a house, and covering m as before; and sometimes they are made by soming a small space with paliandes, and piling up then that roof of beams, earth, and sods upon them. ese delences can be made bomb-proof. Artillery-These desences can be made nomb-proof. Arthury-men working guns on the ramparts are protected from theodies and vertical fire by blindages, made by fixing pallandes on either side of every gun, and forming a black soof above it with the materials above-named: indage is open to the rear, and the gun can be if through the embrasure without hiedrance, is in the trenches, engaged in making the apcourse to a basicged fort, and exposed to a heavy fire in the name of the protected by placing a blindage as the tranch, constructed by frames of timber, and perspectionisty from the sides of the trench

proof a roof made in the usual way.

In those that are are sometimes united to each of itself; sometimes a membrane or f sometimes the pupil is closed, or adverses; and sometimes the opening of the in the right place, so that the rays of it in the middle of the eye. It may also an defect of the optic nerve, or of the brain with it. Blindness may result from di nerve, or of the brain; or from an ab the humours or coats of the eye, interceptis of the light to the optic nerve. Among the lus, inflammation, congestion, softening that organ. The eve itself may be in mation, suppuration, or cancer; see tumours may form on the cornea, and transparency; the humours of the eye thick and turbid; or the opening of the destroyed. Blindness of the destroyed. Blindness often arises from debl optic nerve, occasioned frequently by long-overstraining of the sight. It is in this way tain kinds of occupations are so figurious to-and often cause blindness. Hence it is, tain films or occupations are so injurious at sue and often cause blindness. Hence it is, 100, the northern regions, where the country is long with saow, which reflects the sun's rays, and analy deserts of Africa, blindness is common age blindness is usually occasioned by a driften the humours of the eye, a thickening of the ecrystalline lens, or atrophy of the optic men blindness is an inability to see during the day ? light. Those who have been long impe-cells are often affected in this way. Week Night bles that state in which blindness comes on towards a This may be continued for some time; but at This may be continued for some time; but at ten the eyes become weak during the day size, and it minutes in amaurosis. Proceeding as blindless if from such a variety of causes, it is impossible full anything here regarding its treatment, which with found noticed in other parts of the work. (A AMAUROSIS, CATABACT, OFFURALMIA, EVER, STARR.)
BLIFTORESS, COLOUE. (See Colour SILVEDRISS)
REVENUESS. which will b

BLIFDRESS, COLOUR. (See Colour Silindress)
BLIFDRESS, a small reptile belonging to the fam.
Anguide. There is a great variety of the species in.
Burope, and one of the genus is well known in many
parts of Britain. It is perfectly hermiess, and in no
species are there any poison-fangs. Its testil are
very small, and, when irritated, it attempts to bits, but
a unable to pierce the skin. Its eyes are very small,
and in consequence it is believed to be blind by the
impount. Its tenant hance. The abilindress Russ in gnorant; hence the name. The blindworm liv ignorant; hence the name. The blindworm from he holes, in rocks, under stones, &c., and feed on five worms and insects. It will not tough them when hinds them dead. Its length varies from M to 15 inches, and its thickness is equal throughout its length. Its colour is silvery gray, with a black line along the back. The body is singularly brittle; the tail is easily broken off, but soon sprouts out at the half and at the end of a very is quite renewed. The blindand at the end of a year is quite renewed worm, or slow-worm as it is often called, re wed. Th during the winter, and casts its skin at the begins summer. It is ovoriviparous, and the number of varies from seven to twelve at a birth. One most interesting facts in connection with the bline is that it forms one of the connecting links bet lizards and serpents. The bones of the head of a b lizards and serpents. warm connect it with the linerd family; and sitt there are no external traces of limbs in the size there are the bones of the aboutley; the steries breastbone, and the pelvis, an existing in a

amiliary state.

Bluerza, Mic-ter (Ang.-Sax.), a pushele or ratery badder on the skin containing security branch by retaing the outliele, and may be occased.

## Blister

by a burn or other injury, or by a vesicatory. The term is also applied to the separation of the film or skin of plants, and to the marks on the surface of steel

that has undergone carbonization.

that has undergone coarbonization.

BLISTER, a medicinal agent, which, when applied to
the skin, causes the enticle to rise in small vesicles
filled with a second finid. The most ordinary blister
in use is made from the Spanish fly, Blister-fly, or
Canthagia. It is mixed with a definite proportion of
lard, and war, and used as a plaster. Blisters, however, are applied either in the form of a plaster, or
the liquid state, as may suit the convenience of the
operator. Their object is to draw away, by counterirritation, any inflammatory action from a part to operator. Their object is to draw away, by counter-irritation, any inflammatory action from a part to which direct remedies cannot be applied. Latterly they have been greatly used for the purpose of dis-persing glandular tumours, and also for indolent ulcers. Blisters made from cautharides, when applied for too great length of time, produce distressing affections of the urinary bladder. A piece of silver-paper, or gauze wot with vinegar, is often laid between the blister and the aking when it is made in the product of the serious of the serious of the serious of the serious description and the serious of the ser the akin when it is applied to children and thin-skinned people. Tincture of cantharides, croton oil, strong liquid ammonia, and mustard, are the blisters generally used. Mustard blisters are seldom kept on long enough to produce blisters. In every case a blister should not be kept long applied, and great cleanliness is necessary in dressing the part. Sores which have taken an unhealthy action have often been produced by keeping blisters too long upon children.

BESTERED STEEL is manufactured by heating bars

of malleable iron with cement-powder, in boxes made of fire-brick or earthenware. Cement-powder is composed of nine parts of charcoul, mixed with one part of common salt and wood ashes. A layer of this powder an inch thick is laid at the bottom of each box, der an anen thick is laid at the bottom of each box, and upon that a row of iron bars is placed; more coment-powder is laid over them, and then another row of bars, until the box is nearly filled. A layer of four or five inches of fine sand or loamy earth is placed upon the top of all. The box is then gradually heated to redness, and in about four days it is fully heated through, and the furnace attains its maximum heat. This temperature is maintained for two or three days, when the first test bar is drawn out. The heat is afterwards regulated according to the degree of hardness which may be required. The bars, in this process of comentation, remain eight days for soft steel, and nine to eleven days for harder purposes. When the bars are taken out of the box, their surfaces are found covered with blisters; hence the name. Whilst the iron is being heated with the cement-powder, it undergoes a chemical change. The malleable iron absorbs and combines with about 1½ per cent. of carbon; while and combines with about 13 per cent. of carbon; while a signal amount of carbon combines with a portion of oxygen in the iron, and forms carbonic oxide, which, in its escape from the metal, gives rise to bisters on the angines. Blistered steel is generally employed in the manufacture of hardware. When this process was the manufacture of intraware. When this process were discovered is not known; but at a very early period it was known that charcoal hardened from and gave it a more permanent and better cutting edge. Bistered steel is more fusible than malleable from; its texture is not fibrous, and when a bar is broken, it shows a close fine grain.
Berster-Fly, or Cantharis (Lytta resicatoria), an

insect common to the south of Europe. Its bedy is used for medicinal purposes, having the effect of raising a hister when applied to the skin. It has been observed that the efficacy of the insect increases according to

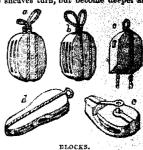

the hest of the country inhabited by it.

Buogs, blok (Fr. bloe; Ger. bloch), in Mar., an adaptation of the principle of the pulley, used in the rigging of thips. By means of blocks, sailors are enabled to raise the sails, and tighten or loosen ropes in different parts of the vessel, with greater facility. They are of various kinds, being called single, double, triple, &c., according to the number of sheaves contained in them. They also receive different names from some peculiarity in their shape; such as the "long-tackle block and the "clue-line block;" or or the prosition in the rigging in which they happen to the placed. There is a great difference in the size and capability of blocks used on hoard ship, and for various purposes in which such mechanical appliances

#### Block

are required. The component parts of a block are the shell, the sheave, the pin, and the strap. The shell is the piece of wood in which the sheave, or pulley, the piece of wood in which the sheare, or pulley, works: it is generally made of elm. Its common form is oval, somewhat resembling a spheroid, flattened at the sides, and perforated with one or more chambers, or mortises, according to the number of sheaves it is intended to receive, in a direction parallel to the sides. The sides of the shell are grooved in two places on either with the sides. side of the pin, to receive the rope by which the block is to be suspended. The grooves are shallow near the pin on which the sheaves turn, but become deeper as they approach the top and bottom of the

The shell. sheaves are circular pieces of lignum vitæ, of different thickness, according to the size of the rope that is intended to work over them; and the circumference is grooved, to prevent the rope from slipping away from

A hole is bored in the centre of the sheave, in which a piece of guu-metal, called the coak, is intro-duced and riveted to the wood; a hole is then made in the coak, exactly in the centre of the sheave, through which the pin by which it is secured in the shell, and on which it revolves, is introduced. The pin is reade of iren, polished as highly as possible, to prevent friction. The strap which surrounds the sides of the block is made of rope or iron, generally of the former; it is formed into a loop at the top of the block, to afford formed into a loop at the top of the block, to amore the means of auspending it in any required position. Blocks without sheaves, perforated with holes only to admit of the passage of a rope, are used in fastening the standing rigging and shrouds of a ship: they are technically called "dead-eyes." Great nicety is required in the construction of blocks, that they may work with facility : they were formerly made entirely by hand, and block-making was quite a separate branch of manufacture, or carried on by those who were engaged in making rests. During the present century. blocks for the navy have been made by machinery; for, in 1901, Mr. Brunel, who had turned his attention to the subject, produced the working model of a machine by which the various parts of a block could be made and fitted with far greater exactness than by hadd. The government, which clearly saw the importance of the invention in this case, caused machines to be erected at Portemouth, under the superintendence of Mr. Brunel, for the manufacture of blocks for the navy; and in the year 1808, after considerable delay, owing to the intricacy and delicate construction of the machinery, they were brought into thorough working order. Since that time, block-making machines have been put up at Chatham and in other dockyards. The first machine erected at Portsmouth, under the management of ten workmen, turned out about 500 blocks a day, at an average cost of about 7s. 6d. per block, effecting a saving of upwards of £20,000 per anoum to the country during the height of the war with France in the early part of the present century. Mr. Brunel received £20,000 for his invention. The method of operation by the muchines is as follows:—The clim is operation by the muchines is as follows:—The emins if irst cut into pieces, according to the size of the blocks required, by a straight saw, working horizontally; the slices thus formed are cut into rectangular parallelopipeds by the action of a vertical circular saw, called the ripping-saw. The piece of wood is then secured immovably to an iron table by the pressure of secured immovably to an iron table by the pressure of soriers, working horizontally, or parallel to the plane of the table, and at right angles to each other, are applied to it one forms the hole from side to side, through which the pin on which the sheave revolves is inserted; and the other makes a hole forming one extremity of the

chamber, or chambers in the case of double and triple consumer, or commorer in one case of double and triple blocks, with which the shall is to be pierced. When this has been done, the chambers themselves are rapidly out out by the action of a steelchisel, the motion of which, as well as that of the block, to enable it to receive the chiesle successive strokes, is regulated by very elaborate and ingenious mechanism. The corners of that the state of the block of the state of the block are then taken off by a circular saw, and it is afterwards brought to its oval shape by what is called the shaping machine: the grooves in the sides of the block are limity hollowed by the scoring machine, and the shell is then ready for the reception of the sheave, whole is fashioned by machinery of less complicated construction. In the illustration given upon the preconstruction. In the interaction given upon the pre-ceding page, are figured,—a, the double block; b, the trable block; c, the clue-line block; d, the long-tackle block; e, the sustch-block. In order to illustrate as fully as the limits of this work will allow, we shall now proceed to give a concise description of the several machines. 1. The straight cross-cutting saw is employed for cutting up into lengths the elm-trees of which the operates in almost the same manner as a carpenter's hand-saw, is only used for the largest trees. The tim-ber, previously rudely squared by the chip-are, is placed horizontally on a low bench, which is situated in the yard, and continued through a window into the sawnill. One end of the tree is brought through the window beneath the saw, which being let down and adjusted upon the place where the log is to be divided, cuts through it. The saw follows its course by its own weight alone, but the attendant can at any time lift up the saw from its work. 2. The cross-cutting circular sage is used for similar purposes as the former machine, but is employed for smaller trees. It is a circular saw, whose spindle is so mounted as to move in any direc tion parallel to itself; the saw all the while continuing in the same plane, and revolving rapidly upon its axis, outs the wood presented to it. By means of a handle, the attendant workman sets the saw against the side of the log, which it partially cuts through; the saw is then applied to the top of the log, next to the other side, and lastly beneath the log if necessary. In this way a saw of moderate diameter will be found sufficient to divide trees of very large dimensions. 3. The reciprocating ripping cut by the present one in the direction of the grain of the wood, first into two, three, or more pieces, in one direction, and afterwards in a direction perpendicular to the former, so as to bring the logs to the size required for the scantling of the proposed blocks. largest blocks are sawn or ripped up by this machine the smaller pieces being cut in the next machines, which are -4. The circular ripping-saw is a circular saw with teeth formed in its periphery similar to those of pit saw. It projects partly up through a bench, beneath which it is fixed to a spindle. The logs being set against the saw, are cut through the length of the grain, and divided into the proper scantling. The wood is guided to the saw by a large parallel ruler similar to those used by draughtsmen. The whole of the abovedescribed machines are used for converting the timber. The following series of engines are employed in shaping and fitting the cut timber into blocks .- 5. The boring michine. The blocks prepared by the foregoing saws are placed in the machine represented at Piate XIX. figs. 1 and 2, where they have two holes perforated through each in different directions; one through the centre, which is intended to receive a centre-pin from behave, and as many others as the block is intended to have sheaves in a direction perpendicular to the former. Figs. 1 and 2, Plate X 1X., are elevations of this machine; fig. 3, an end serew of one spindle fig. 4 is a detached view of another portion, and fig. 5, Plate X X., it is plan of the whole machine, the letters of reference being the same throughout. A B represent two anindies turned by their respective pulleys, a b, and minuted in a frame similar to the mandril of a lathe; both meaning that it is the state of the manufacture and the state of the manner of a carpenter's centrebit. The block marked X is held in an iron frame (E L L) by the end of a carew (F) being forced on the top of it, and the borers

heights from the frame, as is shown in fig. 6. These levers act upon pins fixed in the frames of the two spindles, which frames are fitted upon dovestiled levers act upon pins fired in the transes or the sequentiales, which frames are fitted upon devetailed aiders (I and K), so that they advance towards the block when the workman moves the handles II, at the ends of the levers in that direction; and the bores being in rapid motion by their pulleys, petietrate the wood very quickly. The proper situation for fixing the block that the borders may enter at the right points, is determined in this manner. The frame, E Z, as is shown on the plan, consists of three legs rising from the main frame, and uniting together to support the socket in which the sorew F sets. In this double leg three small screws (d e f) are injected, their heads forming a support, against which one side of the block is firmly held before the sorew F is firmly screwed down upon it, and holds it fast upon the head screwed down upon it, and holds it fast upon the head of a screw (K), which is the support of the block.

The borer C is made to penetrate the centre of the block by a gauge formed from a piece of item; shown separately at fig. 4. This has a groove in it, through which the screw K passes to fix it down to the frame, and a blade (R) standing up perpendicularly just beneath the border D, fig. 1, as shown there at R. One side of the block being pressed in contact with this blade, while the other side is held against the three screws, determines its situation, so that the borers will form the holes at the exact points required. In the same manner, by the gauge R being fixed at a greater or less distance from the screw K, the border C may be adjusted to bore exactly through the course of the side to which it is presented. The length of different sized blocks is accounted for by putting collets of dif-ferent thicknesses beneath the head of the screw K. which raises the support for the block to the proper-height. The slider I, on which the frame of the spindle A moves, is tirmly fixed upon the frame of the machine; but the slider K for the other spindle is formed on the top of a frame (SS), which has a motion on an axis, formed by the points of two scraws (TT) sing through stude projecting from the fer When double blocks are to be bored, the points of the stop-screws m and n are set at a proper distance asunder, and the frame being held first to one of them, bores a hole for one sheave, and being then turned over to the opposite stop-screw, forms a second hole at a proper distance from the first. The screw P has a lever (N) fixed upon the top of it, and loaded at the a lever (N) liked upon the top of it, and lossed as are ends with two weights, in the manner of the fly-press; and the block being held in its true position, the screw is forced smartly down upon it, and, by the momentum of the balls, presses very powerfully upon the wood.

The blocks being thus bored are subjected to the action of-6. the mortising-machine, which is exhibited at Plate XXI., in which a perspective view of this beautiful machine, borrowed from Sir David Brewster's Edinburgh Encyclopædia, is given. The mechanism is nut in motion by an endless strap passing round a drum at A, screwed to a fly-wheel (B), that regulates the movement. This drum turns an axis (D) on the extreme and of which is a crank; this has a long rod extending from it up to a joint at u, which connects it with a frame (E E) fitted between sliders (6.4), and guided by a cylindrical rod (F) sliding through a fixed collar supported by the framing. By this means the frame is moved up and down when the axis D revolves. To this frame the chisels are fastened, and operate upon the block fixed at G in a carriage (H) aliding horizontally in the frame of the machine. three screws the same size as the screw of the boring-machine, and each furnished with the same-sized ring at its end. This enters the impression made by the boring machine, so as to fix the block in its proper position when the screw is turned: this forces the other end of the block against a crossbar of the carother end of the block against a crossbar of the carriage, shown separately on the ground at Y. It has three steel circles or rings (f) fixed to it opposite the ends of the screw e. Each of these rings includes two smaller rings, also made with a sharp edge. Now the pressure of the screw e forces the block against these rings, so as to print their impression in the wood, and by this means the block is held quite fast in the decrease while undergoing the process of morthsing. The are presented to it by the action of two leavers  $(g \in k)$  risps while undergoing the process of mortising. The and k + k, which move on contropins fixed in the carriage has a large double-wormed corew (k) attached frame of the machine at g and h, but at different to it behind, and this is received through a nut; or

Blank

female surew, which is fitted to turn round in a fixed collar, supported by a bar extended across the frame of the machine. To this mut two wheels (g k) are fixed: the former is a large ratchet-wheel, the latter a cog-wheel, which has a smaller one gearing with it. This is fixed on the end of a long axis (k) on the extremity of which is a winch (r). When this is turned round by the attendant, the nut of the screw is turned at the same time, and the carriage moved along sittler backwards or forwards. This motion is only intended to adjust the carriage to the proper point of commencement. The gradual advancement of the block to each cut of the chief is produced by turning the ratchet-wheel g in this manner:—The axis female screw, which is fitted to turn round in a fixed turning the ratchet-wheel g in this manner:—The axis D has an eccentric circle (1) fixed upon it, which, as it revolves, acts upon a roller (K) fixed in one arm of a bent lever, which cannot be wholly seen in the view; the other end of this arm has a rod (m) jointed to it having a tooth in the middle, which engages the teeth of the ratchet-wheel and turns it round a tooth at a time as the rod reciprocates backwards and forwards. The extreme end of this rod rests upon a lever (n),—except when it rises up by being drawn over the sloping side of the tooth of the ratchet-wheel,—the centre of which is a pin fixed in the vertical column of the frame: it is held by a second lever (0), supported on a cock screwed on the frame. The opposite end of this lever is made so thick and heavy, that the weight of it is sufficient to raise up n and m so that the tooth of the latter will be too high to intercept the teeth of of the latter will be too high to intercept the teeth of the ratchet, wheel in its motion. The heavy end of the lever is kept up by a piece of metal fastened to the side of the carriage at p. The screws which fasten this pass through oblong grooves in it, so that it can be fixed at different parts along the length of the car-riage. By this means, when the carriage has advanced far as intended, the loaded end of the lever O tails off the piece p, and disengages the rod m from the ratchet wheel. The fly-wheel and drum, which turn the machine, are, as before mentioned, screwed to lat v, fixed perpendicular to its edge, so as to project gether; but they are fitted on a cyindicial part of; rather before it, being fitted in dovelui notches formed the laxis, so as to turn freely thereon when it is not in the sides of the chisels. These small acribers in the required to turn the axis D and work the machine, descent of the chisel cut or scribe two small clefts, A conical wheel (8), having a hollow axis or tube contrepiece, is fitted upon the axis D so as to slide freely andwise, but is conflued to revolve at the same by fillets inserted into it. The end of the tube of the wheel S is formed into a circular groove, which is embraced by a forked lever (L) centred in the opposite side of the frame. Now, by moving the end of L towards the fly-wheel, the conical wheel S is thrust forward and jammed into the inside of the drum A. This exactly fits the wheel, and the friction caused by the contact of the two conical surfaces is sufficient to work the machine. On the other hand, when the lever Lie pulled eway from the fly-wheel, the coulest wheel is drawn out from the rigger, and by that means the fly-wheel is detached from the axis, so as to revolve upon it freely without turning it; but to prevent any danger of the axis being turned by the friction of the fly-wheel upon it, the wheel S has another cone formed on the back of its rim, the basis of the two being con-joined. When the wheel is drawn back, this cone is ramined into a fixed ring (M) supported by the frame of the machine, so as to be fixed last, and prevent the exis from turning. The mortising-machine is used in the following manner:-The block brought from the boring machine has the print formed by the screw thereof applied to the end of one of the screws at e c. If one double or threefold sheave-block is to be mortised as shown in the figure, the centre serew alone is used to held it in; but if two single sheaves are to be fixed in, then only the outside screws are used, the centre one being left loose. By screwing it tight, the block is fixed between the double-circle prints By screwing it tight, before mentioned, on the bar Y, and stops are situated on the same bar. To guide the block to its proper position, which is, that the hole bered for the commenement of the sheave-hole shall be vertical, sup-pose the block fixed, the handle r is turned till the hole is brought beneath the sliding frame. The childs are now adjusted. These are long square bars onsens are now adjusted. These are long square bars of steel (TT), and are fastened to the frame by a clamp seen separately at X. This goes behind the cross-bar of the frame, and has two square holes through its

ends to receive the chisel T, and two screws to bits it fast in the square holes; at the same time that this keeps the chisels from slipping up and down, it fixes them isst to the frame EE, by drawing the chisels forcibly against the cross-bars by means of the cleanps behind them. The two screws of each clamp being slackened, the chisels are put exactly over the holes which are to become sheave-holes, and acrowed fast. The machine is now put in motion by depressing the handle P. This is at the end of a lever, the fulcrum of which is a pin fixed in the column of the frame at s, and a short arm gives action to the end of the lever L before described, so as to put the machine in motion. At the first descent of the chisels they cut down through the whole depth of the holes previously boxed, so as to give them a flat side when they rise up. The ecceptric circle I, moving the bent lover and rod a, turns the ratchet-wheel round on both, and advances the block a very minute quantity towards the fir-wheel, so that the chisel in descending outs a fresh space, and in ascending the block advances. In this manuer it pro-ceeds with a most astonishing rapidity through the whole length of the intended sheave-hole. At this time the loaded end of the lever o drops off the piece previously adjusted, and raises the rod m, so that the further advance of the block is prevented. When the further advance of the block is prevented. When the boy who attends the machine observes this, he raises the handle P. This stops the machine, as before stated. and the boy takes care to stop it when the chisels are at the highest point, which he effects by a very dex-terous movement. The finished block is now removed and a fresh one put in; the handle r is screwed back to bring the block to the proper point, and the machine starts and proceeds as before. The backs of the chisele have a small piece of steel (t) fixed to them, which thrusts out the chips which they cut; otherwise those would accumulate and wedge up the hole, so as to obstruct the chisel most materially by filling up the space behind it, It has also two small cutters called scribers which include the width of the chip, which will be cut out by the chisel in the succeeding stroke. ingenious device the mortise cut in this machine has its sides as smooth as if they were made by a plane. The back of the chisel is rounded to conform to the hole bored in the boring-machine. To adapt the mortising-machine for different-sized blocks, the crosshar Y in the back of the carriage against which the blocks are pressed, can be fixed by notches cut in the frame at one inch seunder, so as to hold all blocks of different lengths having an inch difference in each. The stops above mentioned to ascertain the position of the block can be fixed upon the cross-bar at any point, either as to height or position sidewise, in the following manner:-The piece of iron W (see the separate view), with a groove through it, carries two vertical pieces (xx), at the upper and lower end of which is a knob: these will place the sides of the blocks applied against them truly vertical. Two small pillars (n,n) are fixed to the cross-bar of the carriage. They have a piece sliding upon them, which can be fixed at any height by screws in the front of the carriage; so that when one is set in the position for a block to be held by one screw, the other will be at the proper place for the other screw. By these means the carriage can be adapted to receive a block of any dimensions, and can guide it to its proper position against the print in the cross-bar. The frame E may have any number of chisels fixed to it, corresponding to the number of mortises intended to be cut. 7. The corner saw cuts off the angles of the parallelopipedon which have passed through the foregoing machines. This is a circular saw, shown at figs. 8 and 9 of Plate XX., where fig. 7 is a plan of the bench, fig. 8 a front eleva-tion, and fig. 9 an end elevation. In these A is a cir-cular saw fixed upon a spindle (a), mounted in an iron trame (B) like a lathe spindle, and turned by a hand-round the pulley C. The block is placed upon an inclined table (D), which presents it to the saw, so se to remove a proper portion of the angle, and prepare it for the shaping-engine, which forms the exterior surface of the block. The block lodges against the

Block ledge (E) of the table, which guides it whilst it is sawn. It is accommodated for blocks of different dimensawn. It is accommodated in blocks of direct dubers sions by placing wooden rulers of proper thicknesses against the ledge B to bring it near to the saw. In one of these machines the ledge E is fitted with con-necting bers in the style of a parallel ruler, so that it neuting pars in the says of a parametric ruler, so that it can be fixed at any distance from the saw, but always parallel thereto. The saw is fixed in a chuck, which is attached to a spindle for sawing, so that it can be quickly removed to sharpen the saw. The limits of this work preclude our giving in full an account of all the operations of these magnificent pieces of mechanism; our readers are therefore re-ferred to Sir D. Brewster's work already mentioned, where will be found a lengthy description, accompanied by some excellent perspective drawings of the machines. 8. The shaping engine, which consists of a double wheel, and contains ten blocks at one time. When these are put in motion, the external faces of the blocks pass under the gouges, which shape them into the required form. 9. The knowing enque, the last machine of this series, is employed to form the score round the block, for the reception of the strap or rope by which it is suspended in the rigging of the ship. The score is a groove deep enough at the ends of the block to receive one half of the rope, but is diminished to nothing where it crosses the pin of the block. With this operation the preparation of the shells of the block is terminated, after which they are trimmed, polished, and finished by hand. 10. The straight saw, for cutting the lignum vite, is a machine somewhat similar to that already described for cutting the elm logs. It is only used to cut out the largest sheaves cause the circular saw to be next mentioned would not act freely through a large and hard substance.
11. The circular saw for converting the lignum vita. is only used for the smaller sheaves. The revolving saw is applied to the outside of the tree, which at the same time revolves upon its own axis, so as to present every part of its circumference to the action of the saw. By this means the saw will cut a tree of nearly as great a diameter as itself. 12. The crown saw works similarly to a trepan, having a centrebit on its axis. The piece of wood being fixed before this contrivance, the saw outs out the circle, and at the same time bores a hole in the centre. 13. The couking engine. This machine prepares the sheave for the reception of a bell-metal bush, or centre-piece, called the coak, one of which is fitted into each side of the sheave to surround its centre pin and avoid wearing. 14. The delling machine bush as a machine bush as the coars. drilling-machine bears a great resemblance to an ordinary turning lathe, which is employed to perforate the three semicircular projections of the coaks, at the same time drilling through both the coaks and the wood of the sheave. 15. The riveting-hummers are two small tilt hammers used for the purpose of riveting the pine which hold the gua-metal coaks into the hole in the sheaves bored by the coaking engine.

16. The broaching engine, where the sheave is fixed to a vertical revolving axis, the borer being brought down into the hole in the centre of the coaked sheave, and broached out to a perfect cylinder. 17. The fuceturning lathe is a lathe furnished with a sliding rest, in which the two faces of the sheave are turned perfectly smooth, and the circumference made truly regular. With this operation is concluded the finishing of the blocks, stells, and sheaves. The iron pins for them have next to be described. 18. The tarning lathe, where the iron pins are turned with a slide rest. 19. The polishing engine consists of three steel dies fixed in a box and regulated by strong screws, to form a triangular opening of any required dimensions. The pin being drawn through these dies, and turned round at the same time, receives a most violent pressure and at the same time, receives a most violent pressure and friction, which burnishes and polishes the whole of its surface in the most complete manner. The dies are of course immersed in oil, to avoid the heating of the pin or dies from friction. 20 is an apparatus for boring large holes in any position, and is used for blocks of a size beyond that for which the regular machines are calculated; some of these blocks being as large as fifth family have in hearth with four increase. 21 The size beyond that for which the regular machines are calculated; some of these blocks being as large as fifty-four inches in length, with four sincaves. 21. The machine for making dead eyes is a most ingenious and to the time of Brunel's invention, block-making by complete machine, whereby the whole of the article is complete machine. The pieces of wood, being sawn to Brewster's Edinburgh Encyclopædia; Eng. Cyclopædia 295

the size, have the holes bored through them in the toe size, have the nones nored through them an analysis boring-machine, for the reception of the rope which is to be reeved through them. The angles are next removed by the corner saw. The pieces of wood are then placed in this machine, which shapes them, and cuts out the score round them.

Mr. Tombinson, in his Cyclopadiu of the Useful Arts, states that "the number of machines employed in making the blocks is forty-four. These are divided into three sets, so that three sets of blocks, of different sizes, may be proceeding in all their stages at the same time, although in some of these stages one machine operates at the same time upon two, or even ten blocks. The different blocks made by these machines are as follows: "Which blocks made by these machines are as follows :- Thick blocks, four varieties, - single sheares, double sheares, treble, and fourfold. The sizes of each variety are from four inches to twenty-eight inches in length; but only the first three varieties are wholly made by the machine, the fourfold being chiefly made by band. But their sheaves are entirely formed by the machines.

These make about		izes
but with narrow sheaves: these are from six to twenty-six inches in length.	48	69
Clue-garnet and clue-line blocks, of pe- culiar construction, introduced by the inventor of this machinery		
Sister-blocks	20	29
Top-sail sheet-blooks Fiddle, or viol blocks Jack-block	20 24	**
Jack-block	20	,,
Total	214	

The number of block-shells of different sizes made by each machine is thus stated :- The first set of machines makes blocks from four to seven inches in length at the rate of seven hundred per day. These have wooden pins. The second set makes blocks from eight wooden pins. The second set makes blocks from the rate of five hundred and twenty per day. The third set makes blocks from eleven to eighteen inches in length, with the pairs at the rate of two hundred per day.—Total, from pins, at the rate of two hundred per day.—Total, fourteen hundred and twenty per day. This collection of machines is one of the most ingenious and complete ever invented for forming articles in wood; so that not only blocks, but other articles in wood, can be produced, the machines performing most of the prac-tical operations of carpentry with the utmost accuracy and dispatch. The largest timber can be converted and sawed up into any scantling by several circular and reciprocating saws adapted to various purposes. Some of the operations performed by the smaller machines are boring, mortising, turning in wood and iron, riveting, drilling, broaching, burnishing iron pins, &c., operations which were formerly supposed to be chiefly or entirely dependent on the skill and dexterity of the workman. These machines are set in motion by a steam-engine of 32-horse power, which is also used for various other purposes in the dock-yard. . . . Brunel was engaged in completing this system from September, S02, to June, 1808, his allow-ance during that time being one guines a day. Such was the importance attached by the Government to this invention, that a complete set of duplicate machinery was erected in the dockyard at Chatham, and kept in constant readiness for action, in case of any accident to the machinery at Portsmouth. Hitherto, however, the duplicate machinery has not been wanted. The muchinery was constructed by Messrs. Mandsley, of the Westminster Road, London. The framing of The machinery was constructed by the Westminster Road, London. The framing of the machinery was of cast fron, and those parts extended and motion were of cast steel." posed to violent and rapid motion were of cast steel."
The construction of blocks, which at first sight appears a very simple operation, which any workman in wood could perform with facility and accuracy, is in reality a very nice bit of mechanical work. The parts must all be fashioned and fitted together with the greatest

-Arts and Sciences; Tomlinson's Oyclopædia of the Useful Arts.

BLOCK, in Com., a heavy piece of timber.

Brock in maritime langua

BLOCK AND BLOCK in maritime language is used when hauling any tackle, halyard, or the like, to which two blocks belong, the two meet and touch, so that they can be hauled no farther.

BLOCK-BATTERY in the military art denotes a wooden battery on four wheels, movable from place to place, whereby to fire en barbe, or over the parapet. The term is sometimes used in galleries and essements. PLOCK-BRUSH, in Her., a hunch of kneeholm, or

bastard myrtle, formerly used by butchers to clean their blocks. It forms a part of the armorial bearings of the Butchers' company.

BLOCK-CARRIAGE, in Artillery, is a carriage used for the conveyance of morters and their beds from

for the conveyance of mortars and their beds from one place to another.

BLOCKEDE, blok-aid', in Mar., the close observation of any port or harbour on the scaboard of an enemy's country, to prevent the entrance and egress of vessels engaged in commerce, or an attempt to relieve the beleaguered town by the introduction of men or provisions. It is effected by stationing menof-war at a short distance outside the blockaded port. -In Mil., towns and forts that are difficult of investment and regular approach by trenches, through being situate in a communding position on a hill or eminence, are blockaded by being surrounded with a cordon of works or redoubts established on the surrounding heights, at the distance of half a mile or more from each other, according to circumstances and the nature of the country. The great object in both cases is to starve the inhabitants and garrison into submission, and thus effect the reduction of the place besieged. Sometimes a blockade must be carried on by sea and land at the same time to render it complete and effiis an at the same time to render it complete and effi-cient; but the term is more particularly applicable to the investment or watching of a port by ships of war. The following is the definition of the word blockade, in the words of Sir William Scott, afterwards Lord Stowell:—"A blockade is a sort of circumvaliation round a place, by which all foreign connection and currencyndence is as far as human connection. correspondence is, as far as human power can effect it, to be entirely cut off." A summary of the whiel A summary of the blief points in international law affecting the relative rights of neutrals and belligereuts in the case of the blockade of the coast of one belligerent power by another, will be found below

be found below.

BLOCKADE, LAW OF.—The law of blockade, as affecting the rights of neutral states which are in any way connected with that belligerent power whose ports are closed by another that has declared war against it, is one of the most intricate subjects in international law, owing to the difficulty of determining on the one hand to what extent belligerents shall be restricted in the exercise of the rights of war as far as neutrals are concerned, and, on the other, to what limits neutrals may proceed, in their relations with the country whose ports are blockaded, without bringing themselves under the power of its adversary. A declaration of war made by one power against another, accompanied by an official notification of the blockade of the ports of one or both of the belligerents, is always attended with serious injury to the commercial interattended with serious injuty to the commercial inter-course between neutral states and the power or powers whose ports are closed. As soon as a blockade is noti-fied, all intercourse between the power whose ports are blockaded and neutral states is at once stopped; but a certain time is given to allow ships belonging to neutral states to clear out of the blockaded ports with the cargoes they have already taken on board, and for the merchant vessels of that power to return home prior to the date from which a strict observance of the blockade commences. For any power to take steps to render intercourse between an enemy's ports and neutral states impracticable, is perfectly consonant with justice, even though such an act be attended with loss and detriment to the commerce of such states: and it is equally fair and right to consider any vessel that attempts to enter an enemy's port, after notice of the blockade has been given, in the light of an enemy a ship, and to treat it accordingly; or to pre-

may be engaged in carrying in munitions of war and provisions; and the power insisting on freedom of intercourse be giving moral support, at least, to the enemy's cause; thus frustrating the designs of the blockading power to a certain extent, and perhaps thwarting a more speedy settlement of the quarrel that might ensue if the blockade were strictly enforced and observed by all parties, whether directly or indirectly concerned. That a blockade may be really effective, whether the a sufficient number of shine surrounding may be engaged in carrying in munitions of war and there must be a sufficient number of ships surrounding the port to render the ingress and egress of vessels either imprecticable, or attended with danger of capture or destruction. It is not sufficient for one power to say that it has notified the blockade of the ports of another power, and to leave those ports unguarded by men-of-war; if so, the right and privilege of capturing any vessel which touches, or even has touched, at any port thus nominally blockaded, which a beliggerent closing the ports of another power asserts, would be unlimited and insupportable. Such a blockade would be merely nominal, and any neutral power would be justified in taking no notice whatever of a mere notification, unless supported by the means of carrying the same into effect by an armed force. An effective blockade depends, therefore, on the actual fact, ac-companied by a proper notification of the same. A mere notification, without armed vessels stationed at the ports which are closed, has been already stated to be useless. There are, then, two kinds of blockade: one, without notification, which ceases on the withdrawal of the ships from the blockaded port, unless caused by accident or a mere change of wind, obliging the blockading vessels to abandon their position for a while; and another, when notification of a blockade has been given to neutral states, and supported by the investment of the enemy's ports by vessels of war. In the latter case, all states are obliged to respect the blockade until an official report of the raising of the same has been received; and this should be made by the blockating power immediately after the cessation of hostilities, although no means exist by which any power may be called to account for neglecting this observance. Vessels belonging to neutral states, that happen to be in any port with their cargoes already on board before notification of the blockade has been made, are at liberty to quit the harbour, even after notification has taken place, under certain restrictions ; but they must not take in any additional cargo, nor is it admissible for the master to make any purchases at that port, except what may be absolutely necessary for the maintenance of himself and his crew. After notification of a blockade has been made, it is manifestly a breach of blockade for a vessel to attempt to enter or come out from my closed port. Any vessel may be lawfully captured which is approaching the harbour with the view of running the blockade at some convenient opportunity; and some assert that a vessel may even be taken and condemned which has just set sail from a neutral port with the intention of entering a port of the enemy's, although it would be a difficult matter to prove that such was the intention of the master, as well as the owners of the ship and cargo, unless the belligerent power effecting the capture had managed to institute a system of espionage at the port from which the vessel had sailed, and at the other principal ports of the neutral state to which it belonged. When any neutral vessel has managed to run the blockade, it is liable to capture, until it has reached its own port, or any other in which it may take shelter; but it is still liable to be taken on again leaving that port, until the cessation of hostilities has caused the blockade to be raised. When a neutral ship is captured in an attempt to violate a blockade, or after having done so, it must be taken by the captor to the naving done so, it must be taken by the captor to see nearest harbour in which a prize-court is sitting, to determine the legality or ulegality of the capture, as the case may be. If the capture prove to be illegally made, the owners can claim an indemnity for determined in the capture of t tion, and any injury done to the cargo; but if it can be satisfactorily proved that a sufficient blockade of the enemy's ports exists, and that some actual breach of the bockade has taken place, with the knowledge and consistence of the master and owners of the ship and cargo, the vessel and its with the other power from holding direct intercourse owners of the ship and cargo, the vessel and its with that whose ports are closed, as the neutral vessel contents are formally condemned and sold for the

## Blockhouse

benefit of the captors; if, however, it can be proved that the master of the ship is alone implicated in the breach of the blookade, while the owners of the cargo with which his vessel is freighted are not in any ap privy to or cognizant of the offence, the cargo is given prity to or cognizant of the onence, the cargo is given up; while, on the centrary, if the owners of the cargo can be proved to be the only parties, that are guilty, and that the master or owners of the vessel have not intentionally violuted the blockade, the cargo alone is taken and the vessel restored. It is perfectly lawful for neutral states to carry on intercourse with a block-aded port by any inland means of communication, and their vessels may land their cargoes at the nearest port belonging to some neighbouring power, and transmit the goods overland. The law of blockade was carried to its highest pitch, and enforced with the utmost rigour and severity, during the struggle between France and Great Britain, in the early part of the present century. The emperor Napoleon issued his present century. The emperor Napoleon issued his famous decrees of Berlin and Milan in 1806 and 1807. by the former of which all vessels trading to British ports were declared subject to capture; and, by a supplementary decree, that any vessels whatever, not possessing certificates from the French consuls at the ports from which they sailed, that no part whatever of the cargo which they had on board was British; and durther, all countries were prohibited from trading in British productions or manufactures of any kind whatever. The English government retaliated by the "orders in council," 1807—1809; but this restrictive policy with regard to neutrals proved so injurious to the trade of this country, that it was subsequently abandoned, in compliance with the representations of the merchants of London and the large mercantile towns, who had petitioned for a repeal of these grders. The present acceptation of the law of blockade may be considered to be founded on the clear and lucid judgments delivered during this period, and up to the close of the war in 1815, by Lord Stowell, then Sir William Scott, in his capacity as president of the High Court of Admiralty. A statement of the laws affecting the right of belligerents to search vessels belonging to the right of heligerents to search vessels belonging to neutral states suspected of enrying "contraband of war" will be found elsewhere. (See Slanca, Right or.)—Ref. Wheaton's Elements of International Law; Hazlitt and Roche's Manual of the Luw of Maritime Warfure; English Cyclopadia—Arts and Sciences. BLOCKHOUSE, thick-hous, a work of defence, formed principally, as the name implies, of logs of timber. It

may be built by itself, in which case it may be looked on as a small independent fort; or it may be situated in the interior of field-works, when it becomes a retrenchment, used for the same purposes as erections of a somewhat similar nature called blindages. (See BLINDAGE.) The blockhouse is generally built in countries where there is plenty of timber, and in situations where light artillery cannot be brought to bear directly upon it. It is for the most part of one story only, and rectangular in form. Strong timbers are fixed in the ground perpendicularly at the angles of the blockhouse, to which the sides are attached, formed of horizontal logs strongly fustened tegether, and pierced at a convenient height with loopholes, from which a at a convenient height with loopholes, from which a fire of musketry can be kept up against assailants. It is generally surrounded with a ditch, the earth taken from which is piled against the lower part of the building, and used to form the roef, being heaped on an interior covering of logs and faggots. The ditch is useful in preventing the close approach of the enemy to set fire to the blockhouse. The entrance, if in the side is notested by blindages, but it is generally made side, is protected by blindages; but it is generally made in the roof, and entrance and egress obtained by means of a ladder. If an upper story be added to the block house, it is usually built so that its four sides overlook the angles of the lower story, being parallel to its diagonals. This enables the defenders to direct their fire against any one approaching the angles of the lower story, which are necessarily out of the line of fire directed from its faces. When the roof is intended to resist artillery and to be shell-proof, it must be made of earth well rammed together, at least four feet in thickness. The AmerRan backwoodsmen and trappers have found these log-forts of great service in their conflicts with the Indians; and they are very skillul in constructing them. Sometimes the blockhouse, in the roof, and entrance and egress obtained by means ful in constructing them. Sometimes the blockhouse,

## Blood

which, in its simplest form, is about eighteen or twenty feet square, assumes a more important character, and is erected for the purpose of resisting artillery. In this case it is built with re-entering angles, which permit a flanking fire of musketry to be kept up to defend the sides of the work, and the walls are made of a double row of upright timbers about two or three feet apart, with the intervening space filled with earth.

BLOCK-SHIP, in Mar., an old ship which, having become useless as a sea-going craft, has been utilized as a defence for great ports or arsenals. The many and rapid improvements that have taken place in naval architecture have caused a large number of English war-vessels to be unavailable otherwise than as block-ships.

BLOCK TIM.—This term is applied very erroneously to the better qualities of tinned iron; but it really means the impure quality of metallic tin, the pure kind

means the impure quarty of metalic tin, the pure kind being called grain-tin.

Bloon, blud (Sex. blod; Germ. blut; Lat. sanguis), a red fluid circulating through the beart, arteries, and veins of animal bodies, serving for the neurishment of all their parts, and the support of life. This nutritive fluid, called scientifically the liquor sanguinis, consists firstly of water, holding, in a dissolved condition, fibrine, albumen, potassium, and sodium, together with phos abutier, potential and solutin, ogether with pros-phorie acid and other substances; secondly of cor-puscles, or globules, which float in the liquor sanguinis. When drawn from the body, the blood undergoes a remarkable change. By degrees it gelatinizes, and forms spontaneously coagulum and serum. Coagulum consists of the fibrine and the corpuscles; serum, of consists of the north and the corpusates; section of water, albumen, and the various saline matters. The corpuscles are of two kinds—red and white, the red being the more numerous. In man, a red corpuscle varies in size from which of an inch to what of an inch. The discovery of the globules of the blood is due to Leuwenhoeck and Malpighi, whose researches were made soon after the microscope was invented. Blood is termed arterial or venous, according to the vessel in which it circulates. Arterial blood is a florid red, with a stronger odour and less specific gravity than the remous fluid. Venous blood is of a cark purple. The scarlet, or arterial blood, which is one degree warmer than venous blood, owes its colour to its undergoing than venous bood, ower is conour to its undergoing contact with atmospheric air in the lungs; it circulates in the pulmonary veius, the left cavities of the heart, and the arteries, by which it is distributed to the different organs throughout the body. The dark purple blood circulates in the veius, in the right cavities of the heart, and the lungs. (See CIRCULATION OF THE BLOOD, RESPIRATION.) There is, again, a difference between arterial and venous blood in respect to the gases which they contain: the first holds a supply of oxygen, the second is rendered impure by the carbonic acid with which it is loaded. (See ARTERY and VEIX.)
Blood is the product of the elaboration of chyle; it
acquires all its nutritive and life-giving qualities
in respiration. By means of the arterial vessels, it penetrates to all the organs, distributing nutrition to penetrates to at the organs, distributing intertain to every organic tissue. It is, moreover, the principal source of animal heat; from it, also, the secretive organs derive their various products, such as saliva, bile, urine, &c. The average quantity of blood in an adult man has been calculated at 28 lbs. or pints. It has been shown that the composition of the blood undergoes a change in various diseases; and, after repeated bleedings, the number of corpuscles becomes repeated bleedings, the number of corpuscies becomes permanently diminished. The colour, as well as the composition of the blood, varies in different sections of the animal kingdom: red in the Vertebrates and Annelides, it is white and transparent as water in Insects and Crustaceans; bluish-white in Mollusca, yellowish in Holothurians and some other Invertebrates. brates. This difference in colour arises from the corpuscles, which are red in some cases, and in others white or straw-coloured, or bluish-white. The temwhite or straw-coloured, or bluish-white. The temperature of the blood of various animals, according to s of Rudolphi and Tiedemann, is-

Sugar Acres

## Blood of Our Saviour

phosphates contained in 4; and as a cheap source of albumen for calico-printing. An effort has been made by M. Brocchierri to utilize the nutritive portions of the blood of animals, by reducing it to a dried and concentrated state. Combined with flour, the crassaconcentrated state. Combined with flour, the crassa-mentum, or clot of blood, is made into light cakes and mentum, or cot of mood, is made into ign cases and biscuits, and, by the addition of sugar, into delicious bon-bons. The larger masses, preserved without flour or sugar, form the basis of soup of a very nutritious quality. Blood is also employed, in conjunction with other animal substances, in the manufacture of prussiste

of potash. (See Potasu, Paussiate of.)
Blood-Baptism.—In the early Church, when any one suffered marty room without having been baptized, he was considered to have been blood-haptized; and hence martyrdom was termed blood-baptism. When hence martyrdom was termed blood-baptism. baptism was regarded as essential to salvation, mar-tyrdom was also considered as giving a title to heaven,

from Mat. x. 39, and similar passages.

BLOOP, CORRUPTION OF. (New ATTAINDER.)

BLOOP, EATING OF.—Under the Old Testament
dispensation, the cating of blood was forbidden to the Jews; and in apostone times the gentiles are ex-horted to abstain "from things strangled and from blood" (Acts xv. 20); but this last seems to have been advised in order to meet the prejudices of the Jews of that period, who were contending that the gentiles should be commanded to keep the law of Moses. some centuries after, the Christian church continued to abstain from blood; and when it was alleged against them that they were in the way of drinking luman blood, they replied that it was not lawful for them to drink even the blood of animats. After the 4th century, however, the injunction came to be considered as merely of a temporary character, and so ceased to be binding.

BLOOD-FLOWER. (See HAMANTRUS.) BLOOD-HORSE. (See HORSE.)

BLOOD-HORSE. (See HORSE.) BLOODHOUSD, blad hound (blood; and Dan. hund, hound) (Canis sanguinarius), a dog of such exquisite and pecuhar scent as to be able to follow the trail, for many miles, of any body bearing about it traces of tresh-shed blood. The genuine bloodhounds are large, strong, and broad-chested; the upper lip large and pendulous; the general colour a deep tan, marked with

BLOODHOUND.

a spot of black over each eye. Formerly this creature was used in recovering escaped criminals. Such matters, at least in England, have become traditions of a past age, and the instincts of the bloodhound have been turned to the more humans and profitable business of the chase.

BLOOD OF OUR SAVIOUR, was an order of knighthood instituted in Mantua, by Duke Vincent Gonçaga, in 1603, on the occasion of the marriage of his son with a daughter of the duke of Savoy. The name was daughter of the duke of Savoy. The name was derived from the belief that the church of St. Andrew, in Mantan, contained drops of our Saviour's blood

### Blood-root

BLOOD-ROOT. (See SANGUINARIA and HEMODO-BACER.

BLOODSTONE, blad'-stone, a variety of chalcedony, of a fine dark-green colour, variegated with small bright-red spots; whence its name. It is also called Astistrope. Being very hard and compact, it is highly valued by seal-engravers, the devices engraved upon it being much sharper and finer than those engraved on other stones of a similar kind. Hæmatite, a brownred mineral, consisting of sesquioxide of iron, is some-times erroneously called bloodstone.

BLOOM, bloom (Sax. bloma, a mass or lump), a mass of iron that has undergone the first hammering, called the blomery. After this process it requires many more hammerings or rollings to render it suitable for

the use of the smith.

Rhoos, in Psint, is a term applied to an appearance upon pictures which resembles the bloom upon the peach or plum; whence the name. It is probably due to moisture in the varnish used in the painting. and may be got rid of by hot camphine being sponged over the surface of the work, afterwards placing the painting in the sunshine to dry.

BLOOMARY, bloom'-a-re, the name by which the old

iron furnace was called.

BLOOMERISM, bloom'-er-ism .- In the year 1849, Mrs. Ann Bloomer, a lady who had been an active promoter of the "Woman's Rights movement" in America, appeared in New York dressed in a novel and fancium costume. It partly resembled the male attire, and consisted of a jacket with loose sieeres, a skirt which descended a little below the knee, and a pair of Turkish tronsers. The grounds upon which Mrs. Bloomer advocated this alteration in ladies' dress were, that since they had resolved to take their places in the world as fellow-workers with men, they ought not to wear a dress that prevented free muscular action. Only a small number of ladies followed the example of Mrs. Bloomer, and those only of the most strong-minded class. Those who were timid and prudent declined to brave the unpopularity and ridicule which the dress brought upon its adherents. Nevertheless, the name of bloomerism attached itself to the principles which actuated all who belonged to the Woman's Rights movement. The first convention of this move-ment was held in New York, about a year after the costume appeared, under the presidency of Mrs. Lucretia Mott. It had for its object the more liberal education of females, advocated their being brought up to trades and professions, and their rights to the up to traces and professions, and their rights to the social and political privileges possessed by the other sex. In New York, the Sibyl, a monthly journal, is still devoted to the advocacy of a reform in ladical dress; and the editorss, a married lady, and several contributors, wear a medification of the Bloomer costinuous traces and the side of the s tume. It is very awkward-looking and ungraceful.

BLOUSE, blows (Fr.), a loose sack-like frock, made of coarse partially-blenched linen, and worn as an overgarment by workmon and peasants in France. The piece of attire called in England the "smock-frock" bears a close resemblance to the blouse. It is princibears a close resemblance to the blouse. It is principally worn by waggoners, brewers' draymen, and farm labourers. The butchers of England, the south of Scotland, France, and Germany, all wear the blue blouse; France, however, is the country where it is most universally worn, as, indeed, France is the country where it was first adopted; for it is nothing else than a medification of the suyon of the Gauls. Under the empire of the first Napoleon, the rural and citizen militia wore the blouse. The French workmen wear it of different colours, but a white blouse is always put on as Sunday dress. A kind of blouse, made of better material than the English smock-freek or continental blouse, is often adopted by tourists.

Blow-Fly,blo'-fli (Ang.-Sax.) (Surcephaga carnaria;

Gr. sarv, flesh, phago, I cat).—A dipterous, or two-winged insect, of the fam. Muscides, of which the common house-fly is the most familiar example. The blow-fly, which is very common in Britain on heaths, in gardens, &c., has a hairy body, with wings that have an expanse of an inch. The face is yellow, the thorax grey with three small stripes, and the abdomen is dark to the tube at an inch from the broad end; to this is brown, which in certain lights has a bine tune, and is covered with shung yellow spots. The eves are always widely separated in both sexes. The larvæ of by the breath, which in the common form is ejected as

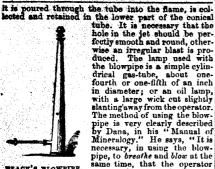

# Blowpipe

the blow-fly feed upon the flesh of animals, either living or dead. Sometimes they are found in mest, the caror dead. Sometimes they are tound in mean, are cap-casses of dead animals, the bodies of living earthworms, and very often upon sheep. The maggots eat their way into the skin of the sheep, which soon die, after suffering great torment. Some parts of England are more intested with these pests than others, and their appearance requires the most untiring attention of the shepherd. Many blow-flies are ovoviviparous, the eggs being hatched within the body of the insect, and their reproduction is very rapid. There is a particular species of this genus which haunts burials

BLOWING - MACHINES, blowing are contrivances, of various kinds, for producing and maintaining a strong current of air for increasing combustion in metallurgical and other processes, requiring intense heat. The simplest form of blowing-machine is the heat. The simplest form of blowing-machine is the ordinary domestic bellows, which is in principle quite inapplicable to metallurgical purposes, from the stream of air being intermittent. By enlarging it, and adding to it an additional expanding chamber, by the rising or falling of which a constant stream of air is maintained, we get the ordinary smith's bellows. This kind, however, is apt to wear out quickly, and has been entirely superseded in all cases where a strong and steady blast is required. The principal kinds of hluwing machines used for blast furposes are these blowing machines used for blast-furnaces are these: The first is simply an air force-pump, worked either by water or steam-power, the air being alternately drawn into and expelled from large cylinders: these generally force the air into a large air-chest, from which tubes to different parts of the factory, leading the blast to various forges or furnaces. The blast is turned off or on by taps inserted in the tubes near the fire-place. In another sort of blowing-machine, much used in iron-smelting, the blast is produced by a series of fans, which revoive at an enormous rate, sucking the air into a tube connected with an air-chest, as in the preceding form. Another kind, in common use on the continent and in America, is called the scaterblowing engine, or trombe. Water, in a finely-divided state, is allowed to fall down a tube, the sides of which contain a series of holes. In falling, the water draws with it a great quantity of air, the accumulation of which causes a draught: the action is analogous to that of the wind produced by a shower of rain. are several other descriptions of blowing-machines. but the above are the most important.

BLOWFIPE, blo'-pipe, an instrument used by workers in metal for soldering on a small scale. It consists essentially of a conical tube, eight or ten inches long, the interior diameter of which varies from half an inch to an aperture the size of a pin-hole. At an inch or so from the small end, it is bent at right angles. It is employed by workmen to direct the flame of a lamp, (generally formed of a bundle of rushes dipped in tallow), upon the portion of solder they are using. It acts by increasing the intensity of the heat of the flame, in the same manuer that the current of air driven through a blast-furnace causes intense combustion of the fuel a biast-furnace causes intense composition of the fuse employed, by increasing the supply of oxygen. In 1738 it was first applied to chemical purposes by Swale, a Swedish counsellor of mines. By the use of the blowpipe there is scarcely a mineral the constituents of which may not be easily discovered. This is effected by combining a small portion of the mineral with a flux, and observing the colour produced, by noticing the effect of heat alone on the mineral, or by reducing it to the metallic state by means of charcoal, carbonate of soda, or some other reducing agent. The blowpipe has of late years become an indispensable adjunct to the laboratory; and the excellent treatises on its use by Berzelius, Plattner, and others, show how much it by herzenus, riaciner, and others, show how much to it valued by chemists of the greatest eminence. The chemist's blowpipe is a modification of that used by the jeweller. The most ordinary form is Dr. Black's, which consists of a straight conical japanned threphate tube, two-thirds of an inch in diameter at the largest only which is closed and one-third of an inch wide at end, which is closed, and one-third of an inch wide at the narrow end, which is open. A small pipe is adapted

the management of the blowpipe in analytical or the management of the blowpipe in analytical opera-tions, it is necessary to study the properties of the dif-erent parts of a flame. On examining a clear candle-flame, it will be found to consist of the following parts:— the bright blue base, merging into a nearly colourless flame surrounding the mass of burning carbon, within which is contained the tallow or wax absorbed by the wick, and converted into a gaseous state by the heat, On directing the current of air through the flame. On directing the current of air through the flame, about the eighth of an inch above the wick, it becomes much elongated, and, owing to the quicker combustion of carbon, much less luminous. The long flame will be seen to consist of two parts,—one blush, the other yellow, at the junction of which is the point of greatest heat. The blue portion of the flame has the property of withdrawing oxygen from bodies submitted to its action, and is thence called the deoxidizing or reducing flame. The yellow portion, having a contrary effect, is called the oxidizing flame. Deoxidation or reduction is produced in the greatest perfection by using a small orifice, and by keeping the substance under examination surrounded by the flame, so as to defend it from the action of the atmospheric air. Good practice is obtained by fusing a piece of tin, the size of a pea, on charcoal, and submitting the melted globule to different parts of the flame. By varying the strength of the blast and the position of the globule, much experience will be gained in reducing or oxidizing, as the metal shows instantly, by its brilliance or dulness, which of the two actions is going on. The chief articles used in blowpipe analysis are—charcoal, well burnt and is produced in the greatest perfection by using a small the two actions is going on. The chief articles used in blowpipe analysis are—charcoal, well burnt and pretty hard; platinum wire, as thick as a stout horsehair; platinum foil; and hard glass tubes, both closed and open. The principal re-agents are carbonate of soda, black flux (which see), cyanide of potassium, borax, microcosmic salt (phosphate of soda and ammonia), all in fine powder. A strong solution of nitrate of cobalt is also useful. The first four are used as of cobalt is also useful. The first four are used as reducing agents; the last four for producing character-istic coloured beads or flames. Reductions are geneis nearly ex-listic coloured beads or flames. Reductions are gene-hausted, the rally performed on charcoal supports. The beads are mouth is again formed by dipping the end of a platinum wire turned filled with air into a hook into the powdered flux, and fusing it in the from the nos-trils, without colourless. If it is at all coloured, some impurity must To understand have been taken up. Having procured a colourless

bead, moisten it slightly, dip it into the assay, and re-fuse it in the oridizing or reducing fiams, as required. Wires are clemed by melting off as much of the glass as possible, and afterwards soaking them in water. The preceding table from Plattner gives the mactions in the two flames, with microcosmic salt and borax, of the more common metallic oxides. It will be noticed that the alkalies, earths, and silicic soid give colourless beads under all circumstances. Their presence is generally tested by the colour imparted by them to the flame. For more particular details, the student is referred to Plattner's treatise on the Blowpipe, a work of wonderful completeness. Potash moistened with hydrochloric acid gives either fame a purple tinge; lithis, red; soda, yellow; strontia, crimson; lime, red, but feebler than strontia; magnesia, with solution of nitrate of cobalt, red; alumina, with nitrate of cobalt, blue. Baryta cannot bead, moisten it slightly, dip it into the assay, and alumina, with nitrate of cobalt, blue. Baryta cannot be detected easily with the blowpipe. Ammonia is see desected easily with the niowpipe. Animonia is easily discovered by gently heating the suspected substance with caustic lime, and holding near it a rod dipped in hydrochloric acid. If ammonia is present, characteristic white fumes of chloride of ammonium are produced. (For the other uses of the blowpipe in

are produced. (For the other uses of the blowpipe in the laboratory, see FURNACES and GLASS-BLOWING.) Blueurs, blub'-her (Ang.-Sax.), the fat of whales and other large sea-animals. Properly speaking, it is the adeps of the animal, and lies immediately beneath the skin and over the muscular flesh. In the porpoise it is a firm and fibrous mass, usually about an inch thick; in the whale its thickness is generally six thick; in the whale its thickness is generally six inches; about the under lip it is two or three feet thick. The quantity of blubber yielded by one of these snimals is generally from twenty to thirty tons, from which from fifteen to twenty-two tons of oil may usually be extracted. The use of the blubber to the animal seems to be partly to poise the body, and render it equiponderant to the water, partly to keep the water at some distance from the blood, and so prevent chill, and partly to reflect the hot steams of the body, and so redouble the heat; since all fat bodies are less

sensible of cold than lean ones.

sensible of cold than lean ones.

Blue, bloo (Sax, bloo; Ger. blau), one of the primary solours. (Sec Colour.) A great variety of blue pigments are used in the arts: they are obtained from both mineral and vegetable sources. Prussian blue, one of the most generally used, is made from a mixture of prussiate of potash and a salt of iron. Indigo is also much used when dissolved in sulphuricated. acid. The Covenniers, in Scotland, chose blue for their colour, in contrast to the red of the king stroop-ers; and at the battle of Bothwell-bridge their standard ers; and at the battle of Bothwell-bridge their standard had a deep adging of blue. From that time blue was adopted by the Whigs as the distinctive colour of their party: hence the term "true blue." After the landing of William III., orange, or buff, was added to the blue, in compliment to the house of Hanover; and these two colours have been retained by the liberal party ever since. The cover of the "Edinburgh Review," and the banners at contested elections, are examples of this party feeling.

BLUEBKARD, bloo'-beerd, is the name of a well-known old Freuch tale of fiction. The hero of the story is a

old French tale of fiction. The hero of the story is a Chevalier Raoul, who had a blue beard, whence his designation. In order to test his wife's curiosity, he intrusts her during his absence on a journey, with the key of a chamber which she is by no means to enter. Unable to stand the test, however, he discovers on his return what she has done, and puts her to death. Several other wives share the same fate, until the seventh, who is rescued by her brothers when about to be put to death; and Bluebeard is slain. The German author Tieck has worked up these materials into a drama, entitled "Phantasus."

BLUE-BLUD (Sialia sialis). — An American bird, closely resembling in its habits the English robin.

BLUE BOOKS is a name frequently given to the re-ports and other documents printed by parliament, from their being usually covered with blue paper. The proceeding away covered with blue paper. The practice of printing their proceedings was lirst adopted by the House of Commons in 1681, and since that time they have increased and extended, till now the printed papers of a session sometimes occupy 60 or 70 large folio volumes. They comprise reports of committees and commissions of inquiry, colonial reports, accounts

and papers relating to trade and finance, the satinates and accounts of public moneys, the votes and proceedings of the house, public bills, &c. The papers of seach session are arranged so that they may be bound up in regular order, and have an index, by means of which any paper may be at once found. General indexes have also been published from time to time, extending over a series of years. The blue books contain an extraordinary amount of information in all departments of legislative inquiry;—in law, history, the privileges of parliament, negotiations with foreign powers, and every variety of statistics. These are, however, so mixed up with much that is of little or no value, that they are in a great measure buried. The statistical they are in a great measure buried. The statistical they are in a great measure buried. The statistical returns, in particular, are by no means so useful as they might be made if they were prepared in a regular and uniform manner. They are moved for at different times and for particular objects: one dates from lat January, another from 5th April; one calculates the value of exports by the offlicial, another by the declared or real value; one shows the gross, another the net revenue; one includes the United Kingdom, another exceeds only to Great Britain. In order to obviate in tends only to Great Britain. In order to obviate in some measure these defects, the statistical department some measure these defects, the statistical department of the Board of Trade was formed in 1832, for preparing regular accounts of the revenue, commerce, and navigation of this and other countries. With a view further to improve the character of parliamentary returns, the printing committee, in 1841, suggested—"1. That every member be recommended, before he gives notice of a motion for a return, to consult the librarian of the House of Commons; 2. that, after the order for a return has been made by the house, the librarian do prepare, when necessary, a form, to be submitted to Mr. Speaker for his approval, and that such form shall be forwarded, with the order, in the usual manner; 3. that, before any return which has been presented to the house shall be ordered to be printed, it shall be inspected by the librarian and approved by Mr. Speaker." These recommendations have since been repeated by the printing committee. The heavy expense incurred in printing is another great objection to the present system of preparing the blue books. Many maintain that properly-prepared abstracts would be infinitely more useful than the reports as at present issued. "I speak from some personal observation," says Lord Stanley, "when I say that, at a cost hardly greater than that of those desultory, fragmentary, isolated returns, it would be possible to present to the nation such a yearly resumé of administrative statistics as should, to a very great degree, supersede the prethe house shall be ordered to be printed, it shall be as should, to a very great degree, supersede the present system (if system it can be called) of moving for returns as and when they are wanted. . I think a statistical department desirable, instead of a statistical branch in every department; because the former method gives better security for unity of plan, and because the work will be best done by those whose sole and undivided business it is."—Speech at British Association, 1856.

BLUEBOTTLE-FLY. (See FLESH-FLY)

BLUE BREAST (Motacilla succica), one of the English names of a pretty bird which forms the link between the redstart and the lapwing. It resembles both birds closely, and is sometimes called the blue-throated robin, and sometimes the blue-throated redstart. The blue breast is found in the same countries where the redbreast is found, and particularly on the borders of forests. It is very rare in this country: in Yarrell's "British Birds" mention is made of four cases in which blue-breasts have been shot in England. The song of the blue-breast is very agreeable: it resembles one nue-oreast is very agreeable; it resembles two voices,—one deep like the humming of a violin string, and the othersoft, like the sound of a flute. The blue-breast builds its nest in bushes and in the holes of trees, and lives upon flies, worms, and the larvæ of insects. It is also said to feed upon elder-berries. It lays six eggs, which are of a greenish-bine colour.

Blue coat School. (See Christ's Hospital.

LONDON.)

BLUE COPPER, a fine blue mineral, consisting of sulphide of copper. It is also known as indigo-copper.
BLUE COPPERS, sulphate of copper, so called to
distinguish it from green expers, which is sulphate
of iron. (See COPPER, SULPHATE OF.) It is also called blue vitriol and blue-stone.

## Blue Gowns

Blux Gowns, a name commonly given to a privi-leged class of beggars in Scotland, who were king's bedesmen, and received a small royal bounty. Blux John, a name given by miners to the blue variety of Derbyshire or fluor spar. It occurs in

oubical crystals or in granular crystalline masses, and is much used for making ruses, cup, and other ornaments. It is found principally at the Blue John mine at Castleton, in Derbyshire, and in the lead-mines of Alston Moor, in Cumberland. (See Fluor Spar.) This material is daily becoming scarcer. It requires great skill in working, owing to its brittleness.

BLUE MANTLE, the heraldic title of one of the pur-

suivants at arms attached to the Herald's College.

(See PURSUIVANT.)

BULL-STOCKING is a name given to a female who gives herself up to learning and literature, to the neglect of her womanly duties, and makes a show of her acquirements in a pedantic manner. The name originated in London about 1780. It was much the fashion at that time for ladies to have evening assemblies, where they might mingle in conversation with literary and other distinguished men. An eminent member of these societies was a Mr. Stillingfleet, who always wore blue stockings; and such was the excellence of his conversation that, when absent, the ladies were wont to say, "We can do nothing without the blue stockings." Hence these societies came to be called Bhue-Stocking Clubs.—Ref. Boswell's Life of Johnson.

BLUE-STONE .- Sulphate of copper. (See BLUE COP-

BLUE TIES. (See TIES.)
BLUE VERDITER, a fine blue pigment, with a slightly greenish tinge, prepared by precipitating the hydrated oxide of copper from the nitrate of copper solution left as a by-product in silver-refining, by means of potassa. Care must be taken to add an excess of potassa, otherwice a basic salt of a different colour is produced. Blue verditer is much used by paper-stainers and artists, but its use as a pigment should be avoided, as it is very liable to turn black when exposed to the action of sulphuretted hydrogen.

BLUE VITRIOL. Salphate of copper. ( See BLUE

COPPERAS.

BLUFF, bluf (Ang. Sax.), a high bank, almost perpendicular, projecting into the sea; a high bank, presenting a sharp front.

BLUING, the process of heating steel or iron until it BLUNDERBUSS, blun'-der-bus (Ang.-Sax. blunder,

and Dn. bus, a tube), a short fire-arm of large calibre, widening towards the muzzle, adapted for discharging many bullets at once, so that, without any exact aim, there is a chance of one or more of the bullets hitting the mark.

BLUSHING, blush ing (Dan. blussen, to blaze or glisten), is a sudden suffusing or reddening of the face, excited by a sense of shame, confusion, or surprice. It is produced by an increased flow of blood into the capillary vessels of the face and neck; and besides reddering, it creates a sensation of heat in those parts. It is occasioned by the mental shock acting upon the brain, and, withdrawing the nervous energy which ordinarily contracts the muscular coats of the bloodvessels of these parts, whence the blood is permitted to flow with greater violence through the

Tessels.—Ref. Chambers's Encyclopædia.

BOA CONSTRICTOR, bo'-à con-stric'-tor.—This encranous reptile is found in the interminable marshes of New Guinea, and other hot portions of the American continent, in India and the Indian islands, and in Africa. The branches of the upper and lower jaw of this creature, as well as the bones of the palate, are armed with recurved and pointed teeth, forming four rows above and two below. The pedicle of the lower jaw is moveble, which itself is almost wholly suspended to another bone, analogous to the mustoid, attached to the skall by muscles and ligaments. The branches of the lower jaw are not united, and those of the upper new are attached to the inter-maxillary bone only by ligamenta, so that these animals can expand the mouth sufficiently to swallow begies much larger than them-selves. The ground-colour of the boa is most frequently

# Boarding

variegations, leaving large open oval spaces of the variegations, leaving large open oval spaces of the ground-colour at regular intervals. Boss have been reported, by credible authorities, as reaching the examining to read of their reaching sixty feet in length. Indeed, if we go back to the period when home was a great city, we shall read of one that had it had not the shores of the Bagradas, and that measured a hundred and twenty feet in length. All the wespons the army of Regulus was able to bring against the the army of Regulus was able to bring against the monster were of no avail, and it was not slain till it monster were of no avail, and it was not slam till it had destroyed several battalions, and the siege-engines, loaded with ponderous stones, were levelled against it. It is certain, however, that this bos, if not a pure invention, has been lengthened outrageously. Actually, the bos constrictor possesses enormous strength, appetite, swallow, and powers of digestion. They have been known to swallow whole goats and pics, beginning the property in the property of the property and gradually surjours it does not be supported by the property of the property and gradually surjours it does not be property and gradually surjours in the property of the property and gradually surjours in the property of the property and gradually surjours in the property of the propert the prey at the muzzle and gradually sucking it down. In December, 1861, a boa constrictor, confined in the In December, 1801, a non construct, compet as any Jardin des Plantes, swallowed the blanket provided for its warmth, and, after retaining the indigestible meal for four weeks, disgorged it: it died shortly afterwards. There are several other of the box species, besides the above. The spotted box (Box reytale) of South America, the ringed box (Boa centhria) of the same country, the embroidered box (Boa Phrygia) of the fast Indies, the canine box (Boa canina), and the garden box (Boa hortulona). The embroidered box is supposed to be the most splendid of the tribe; it is about four feet long, the ground-colour is white, the back tinged with golden-brown, while along the whole of the upper part is a series of black variegations bear-ing a striking resemblance to embroidery.

BOAR, bore, the male of swine. (See Hog.)
BOAR, WILD (Sus scrofa).—All the varieties of the
useful gen. Sus that are now seen in civilized countries, owe their origin to the wild boar, which is a native of nearly all the temperate parts of Europe and Asia. It was formerly a beast of chase in the woods of this country, and, at the present day, it is bunted in India and in many parts of Europe. It is generally more and in many parts of Europe. It is generally more gaunt and bony than the common bog, and its muscular strength is greater. When about a year or two old, the hide has a yeilowish-brown hue; but, in time, this changes to a dark brindled grey. There is a fine soft hair, of a woolly nature, next the skin, between the bristles. The snout of the wild boar is rather longer than that of the common hog; but the chief difference lies in the savage disposition of the former and the extraordinary length of his tusks. males are mild, except when their young are attacked. The tusks of the wild hour are long, curved, and sharp, and are capable of inflicting severe and fatal wound After they are five years old, however, these tusks begin to turn up, and are not such formidable weapons. Buffon says of wild boars: "These animals, when they have young, form a kind of flock, and it is upon this sione that their safety depends; when attacked, the largest and strongest front the enemy, and by pressing all round against the weaker, force them into the centre." On account of the excitement and danger connected with wild-boar hunting, it has been at all times a very favourite sport. The ancient Romana used to hunt them on foct with large spears. In later times, William the Conqueror punished, with the loss of their case all are all the spears. of their eyes, all persons convicted of killing the wild boar, the stag, or the rochack. (See Hog. Sus.)
BOARD, bord (Sax. bord, a table; Fr. bureau), is a

term usually applied to certain individuals who, in a collective capacity, are intrusted with the management of some public office or department. Thus, the lords of the Treasury, the commissioners of customs, when met together for the transaction of the business of their respective offices, are styled the Board of Treatheir respective offices, are styled the Board of Tressury, Board of Customs. It is also used to designate the persons appointed by competent authority to manage any private business or speculation,—as a bank, railway, or such like; the directors of which are styled Board of Directors.

BOAPDING Logic line was approached a styled to the

BOARDING, bord'-ing, an expression applied to the attempt to carry an enemy's vessel by assault. It was of frequent occurrence during the war with France, vellowish-grey; and disposed along the entire length in the early part of the present century. After the

## Boarding-Pike

some time, and the contending vessels have drifted closely together, in the course of the action, an oppor-tualty is cought to attach the ships together by means tunny is sought to attach the sups together by means of grappling-irons. A party of seamen and marines, already told off for the purpose, then spring on board the submy's ship, and a furious hand-to-hand encounter takes place, with cutlasses, pistols, and pixes, which is apsadily terminated by the success on repulse of the attacking party. As the French soldiery dreaded to cross beyonets with the English troops during the Peninsular war, and turned as soon as they were near enough to see the eyes of the approaching human avaianche, so the French sailors could seldom withstand the irresistible rush and hearty cheering of the British as they swept the decks of their paralysed defenders, and drove them pell-mell below. Boarding is generally adopted by privateers in the capture of merchant vessels. It is thought by competent judges, among whom is Sir Howard Douglas, author of a work entitled "Warfare with Steam," that boarding will be as much resorted to when steam vessels of war approach as much resorted to when steam vessels of war approach closely to each other in an engagement, as in the smart frigate-actions of former days. It is therefore recommended that all vessels should be well provided with the necessary appliances for attack by, and defence against, boarding, for the latter of which a plan is suggested of barricading the quarter-deck and forecastle, to afford means of continuing resistance, should the main deck be carried. But in consequence of the results of the battle of Hampton Roads (March 9, 1862), between the Merrimac, of the Confederate States navy, and the Monitor, of the United States navy, both iron-clad ships, heavily armed, and protected with iron shields and defences, under cover of which the guns worked, which battered each other with heavy ord-nance for five hours without material injury on either side, an entire change in naval warfare and tactics must take place; and as low iron ships, with cupols shields, on Captain Coles's plan, in which the men who navigate the vessel and work the guns are out of sight, will now take the place of wooden ones in our own navy, as well as in the navies of all maritime powers, it is manifest that boarding can never again be put in practice in vessels built on these principles, but that it must be numbered among the traditions of past

BOARDING-PIRE, in Mar., a weapon formed of an iron spike fixed on an ashen staff, used by sailors in boarding an enemy's ship. It is frequently called a half-pike, from its having a much shorter staff than the whole pike.

BOARD OF ADMIRALTY. - A department of the government which has the management of all matters government which has the management of all matters connected with the royal navy. It exercises the powers which formerly were vested in the lord high admiral; and its members are styled the "Lords Commissioners of the Admirally." They are six in number; and the first lord is always a member of the cabinet. It is the first lord that principally exercises the powers of the office. He is to all intents and purposes the lord high admiral, the other lords acting merely as his advisers and council. It is he that is held responsible in par-liament for the conduct of this branch of the public service. Of the five junior lords, four are always naval or sea lords, two of them generally admirals, and the fifth is a civil lord. This board has the management of everything connected with the navy, both in war and in peace. By their orders ships are built, repaired, sold, or broken up; put into commission or out of commission; armed, stored, and provisioned; employed at home or on foreign stations. Repairs, alterations, and improvements in the dockyards are under their direction; and all inventions and experiments relating to naval matters are laid before them for approval. All orders and instructions to officers emanate from them: and all official returns from the fleet, and every practical detail respecting the condition and discipline of the ships, are addressed to them. All naval honours, proand by their recommendation all pensions, gratuities, and appointments emanate from this hoard; and by their recommendation all pensions, gratuities, and appearantmentions are granted. Under the six lords are two secretaries in-chief, who manage the daily work of the office. The lodds of the Admiralty resign with the ministry,—an arrangement that gives rise to many crils. The salary of the first lord is £4,500, and

## Boar's Head

his official residence is the Admiralty, Whitehall Each of the junior lords has a salary of £1,000, and an official residence, or, in lieu thereof, £200 additional.

BOARD OF ORDRANCE.—A department of the government, which has now been abolished, but which has the meanagement of all matters relating to the artillery and engineering corps of the British army. It consisted of the master-general of the ordnance, who was usually a distinguished military officer, and who, in all matters connected with the discipline, regulation, and distribution of these corps, exercised supreme authority; the surveyor-general, the clerk of the ordnance, and the principal storekeeper, all of whom held their appointments under the great seal during pleasure. During the Crimean war the defects of this board became very manifest, and it was accordingly dissolved, and the duties of the master-general distributed among the different departments of the War-office.

BOARD OF TRADE AND PLANTATIONS.—A department of the government which may be said to have originated in 1660, when Charles II, erected two separate councils, one for trade and another for plantations. sundry subsequent changes, the present department was established by order of council in 1786. In reality the board is a permanent committee of privy council constituted for the consideration of all matters spe cially relating to trade and the colonies. It consists of a president and vice-president, appointed by the queen It consists of in council, and certain other members, who have exofficio places at the board. These are the lord chancellor, the first lord of the Treasury, the principal secre-taries of state, the chancellor and the under-treasurer of the Exchequer, the speaker of the House of Com-mons, chancellor of the duchy of Lancaster, paymaster of the forces, master of the Mint, and such officers of state in Ireland as are privy councillors in England. The precident and vice president form nominally the board, and transact on their own responsibility all such general doties as relate to the trade and com-merce of the United Kingdom, and advise with the other departments of the government upon these matters. They also superintend the conduct of all bills and questions before the parliament as relate to commerce, and exercise some control over private bills so far as the protection of the public is concerned. Another department has also been added to the Board of Trade,-that of the regulation and control of railways. They appoint inspectors of railways, approve or disallow by-laws, and require detailed returns of traffic and of the rates charged. They have also the general superintendence of all matters relating to morchant ships and morchant seamen. A department for the collection of statistics was formed in connection with this board in 1832. The president has a salary of £2,000; the vice-president, who is also paymater-general, has for both offices £2,000; and the two joint secretaries £1,500 each.

BOARDS, SACRED, were small pieces of wood, which were struck together for the purpose of assembling the people to worship, before the use of bells. In some Roman Catholic countries such boards are still employed during Passion-week, as the noise of belle is considered to be unsuitable for the occasion; and they return to the bells on the first day of Easter.

BOAR-FISH (Capres), a fish of the Dory fam., which takes its name from the resemblance borne by its mouth to the snout of the hog. Its firs are covered with rough scales, and it has no spines along the dorsel or anal fine. The eyes are very large, and placed far forward. It is of a carmine colour, lighter below, and with seven transverse orange bands on the back. It is a well-known inhabitant of the Mediterranean, and is very rarely seen on the British coast. Its fiesh is of poor quality.

Role's Heap, in our ancient customs, was the first dish on Christmas-day, and was carried up to the principal table in the hall with great state and solemity. A carol which was sung on this occasion was as follows (See CHRISTMAS.)

"The bore's head in hands bring I
With garlandes by and rosemary;
I pray you all eyings merily,
Qui setis in convito.

## Boat

The bore's head I understande, Is the chefe servyce in this lande; Loke wherever'it be fande, Servite cum cantico

Be gladde, lordes, both more and lasse, For this hath ordayned our stewarde, To chere you all this Christmasse, The bore's head with mustarde."

Boar, bote (Sax. bot), a small vessel propelled on the water by rowing or sailing. There are a great many kinds of boats, the construction and machinery of which are very different, according to the purposes for which they are intended. Thus, they are occasionally slight or strong, sharp or flat-bottomed, plain or ornamented; as they may be designed for swiftness or burden, for deep water or shallow, for sailing in harbour or at sea, and for convenience or pleasure

BOATBILL.

BOATBULL, bote'-bill (Cancroma cancrophaga), an inhabitant of Cayenne, Guiana, and Brazil. It is about the size of the domestic hen. beak resembles boat reversed, having a strong keel-like ridge down the middle of the upper mandible. The food and general habits of this bird place it among the herons. It chiefly lives by the

sides of rivers. BOATEGOX, bote'-hook, an iron hook, with a sharp spike on its hinder part, fixed upon a long pole or shaft, by the help of which a person in a boat may either hook anything to confine the boat in a particular place,

noor anything to commute the boat in a particular place, or push her off with the point.

BOATING, boi-fing, was a severe punishment inflicted by the ancient Persians on capital offenders, in the following manner:—The condemned person being his on his back in a bont, and having his hands stretched out and tied fast on each side of it, had another boat put over him, his head being left out through a hole made for that purpose. In this posture they fed him, till the worms which were bred in the excrements he voided as he thus lay, entirely consumed his howels, and so caused his death, which usually took place in about twenty days.

BOATING.—A boat is managed or propelled by either sails or oars. When the art is pursued by means of sails, it is termed yachting; when the propelling power

sails, it is termed yachting; when the propeiling power is that of oars, the art is termed rowing. (See Rowling and Yachting.)

BOAT, LIFE. (See LIFEBOAT.)

BOAT-LOWERING APPARATUS.—Every ship of war carries along with her boats for particular services; and every passenger-vessel is compelled by law to carry a certain number of boats. The ropes and pulleys used in letting down these boats from the crange or daying the compelled by the carry of the crange of daying the compelled by the carry of the crange of daying the compelled by the carry of the crange of daying the carry of the crange of daying the carry of the crange of daying the carry of the in letting down these hoats from the cranes or davits into the water constitute the boat-lowering apparatus. The means by which boats were formerly lowered were very inefficient; but great improvements have taken place of late years. When boats had to be lowered in place of late years. When boats had to be lowered in any emergency, such as a shipwreck, great difficulty was found in extricating them, and they often capsized in their descent, plunging their occupants into the water. Lacon's friction-break and Kynaston's discongaging hooks were two of the earliest attempts at amelioration. By the former, one man can regulate the rate of a boat's descent, and by the latter, hoats can be both raised and lowered more quickly. Clifford's apparatas, which is now supplied to many ships of war, passenger-ships, and merchant-ships, is considered one of the most valuable. By means of it, the boat is lowered and disengaged by one man seated in the bost.
Experiments were tried on board of H.M.S. Princess-Boyds, in 1856, by order of the Admiralty. Twelsteness got into the starband cutter when she was hanging from the dayits. She was quickly and steadily lowered by one man into the water, a distance of 40

## Bodkin

Many lives have been saved by the use of three tons. this apparatus.

BOATSWAIN, bote'-sin, a warrant officer in a ship, who has charge of the boats, sails, rigging, colours, suchors, cables, and cordage. It is the business of the officer to summon the crew to their duty, and to maint with his mates in the working of the ship

BOATSWAIN'S MATE is an assistant to the boatswain in all the above-mentioned duties, with the disagreeable addition of inflicting all punishments to which the men are subjected.

BORBIN-NET. (See LACE.)

BOBSTAY, bob'-stai, in Mar., a rope used to confine the bowsprit downwards to the stem or cutwater, and to counteract the force of the stays of the foremast, which it draws upwards. It is fixed by passing one of its ends through a hole bored in the fore part of the cutwater, both ends being spliced together, so as to make it twofold, or like the link of a chain. A deadeye is then fixed in it, and a lanyard passed through, which communicates with another dead-eye upon the bowsprit. This is then drawn extremely tight by the help of mechanical powers.

Boc, Bock-LAND, or BOOKLAND, in the Saxon time, was what we, at the present day, call freehold land, or land held by charter; and it was by that name distin-guished from folk-land, which was copyhold land.

Bode's Law, bodes'-law, in Astron., an arithmetical formula which approximately expresses the distances of the planets from the sun. Kepler led the way to its discovery in an attempt to find a general law by which the distances of the planets from the sun were governed, by showing that there was an undue space between the orbits of Mars and Jupiter, in comparison with the relative distances of the plauets from the sun. This caused him to conjecture that a planet hitherto an-observed really existed, having its orbit between those of Mars and Jupiter; and in 1772, this formula, known as Bode's law, was enunciated by Bode, who boldly declared that Kepler's idea would be found to be an actual fact. The law itself is as follows:—Supposing 4 to represent the distance of Mercury from the sun, the distance of the other planets is obtained by adding to this number a geometrical series, of which 3 is the first term, increasing by the ratio 2. Thus, the dis-tances of the planets from the sun are respectively represented as follows; and, for the sake of comparison, the actual mean distances from the sun are given in another column, calculated on the supposition that the distance of the earth is represented by 10.

NAME OF PLANET.	NAME OF PLANET, Distance according to Bode a Law.			Actual Mean Distance
Mercury	. 4	=	4	3.87
Venus	. 4+ 3	=	7	7:23
The Earth	. 4 + (3 ×	2) =	10	10.00
Mars	$.4 + (3 \times$	4) =	16	15.23
Supposed Planet }	4 + (3 ×	8) =	28	26.25
Jupiter	$4 + (3 \times$	16) ==	52	52.03
Saturn			100	95:39
Uranus	$.4 + (3 \times$	61) =	198	191.83
Neptune	$.4 + (3 \times 1)$	(2S) ==	388	300.00

That there must be some truth in the system above given, is proved by the discovery of the sixty-nine asteroids (see ASTERIOTES) since 1800, which fill the place that Kepler supposed to be occupied by a planet. There is no very great deviation from the numbers arbitrarily laid down, except in the case of Neptune. The satellites which revolve round Jupiter and Saturn follow a similar

law in their respective distances from their planets. Bodies, Regulable bod'-eez, in Geom., a term applied to five solids; as the icosuhedron, with twenty regular pentagonal faces; the dodecahedron, with twelve triangular faces; the octahedron, with eight triangular faces; the cube, or hexabedron, with six square faces; and the pyramid, or tetrahedron, with four triangular faces.

BODKIN, bod'-kin (Ang.-Sax.), a large kind of needle used by the women of antiquity for the same purposes as they now are, and also in fastening the hair. It was termed belong with the Greeks, and by the ancient . Romans acus. These instruments were made not only lowered by one man into the water, a distance of 40 of metal but also of bone, wood, and ivory. The fashion feet. The boat, the men, and the gear weighed nearly of fastening up the hair behind by means of the bodking

304

#### Bodle

The term still prevails in Ituly and parts of Germany. bodkin applies, at the present time, more particularly
to a sharp pointed instrument
used for piercing holes in cloth.

BODKIN.

Formerly the term was given to a dirk or dagger; and in Shakspere, Hamlet is found Shakspere, Hamlet is found saying "Who would bear the whips and scorns of time; The oppressor's wrong, the proud man's contumely, . . . When man's contumely, . . . When he himself might his quietus make with a bare bodkin." is also the name of an instrument with an eye, for drawing tape, thread, or ribbon through

BODLE, or BODDLE, bo'del, an ancient Scottish copper coin, of the value of two pennies Scots, or the third part of a halfpenny sterling. It is said to have been named after a master of the mint of the name of Bothwell.

BODLEIAN LIBRARY, 3od'-le-in, the public library of the university of Oxford, so called from Sir Thomas Bodley, by whom it was restored in 1597. He pre-sented to it a large collection of books purchased on the continent, and valued at £10,000. Other collections were sent in to such an extent that the old building soon became insufficient to contain them; and a new wing was added to it by Sir Thomas, the foundationstone of which was laid in 1610. He also on his death, in 1612, left a considerable estate to the university, in lands and money, for salaries, repairs, and new books. Among the more important collections that have since been added to it are those of the carl of Pembruke, John Selden, Archbishop Laud, Sir Thomas Roe, Sir Kenelm Digby, General Fairfax, Richard Gough, and Francis Douce. The library has also been largely increased by purchases, and by being entitled to a copy of every work printed in the United Kingdom. At present it is estimated to contain about 265,000 printed volumes, and upwards of 22,000 in manuscript. All members of the university who have taken a degree are admitted to the use of the library; and literary are admitted to the use of the interry; and interary persons properly recommended are also allowed to consult the books. No books are allowed to be taken out of the library. It is open between Lady-day and Michaelmas from 9 in the morning to 4 in the afternoon, and between Michaelmas and Lady-day from 10 to 3. In terms of a statute passed in 1856, a reading-room has been attached to the library, open throughout the year from 10 in the morning to 10 in the evening.

Bopy, bod's (Ang. Sax.), a term very variously used. In Phys. it denotes a solid, extended, palpable substance of three kinds; as a soft body,—one which, yielding to a blow, undergoes a change; a hard body,one which remains unaltered after being struck; au elastic body,—one whose form changes upon being struck, but recovers again when the impelling force is removed. With respect to animals, body signifies the frame, the material substance, in contradistinction to the living principle in beasts and the soul in man; in other words, matter as opposed to spirit.

BODY COLOURS, pigments used in executing he-raldic paintings and illuminated work, in which the colour is required to be laid on in such a manner that it may form a thick uniform coating over the paper or vellum on which the outline is traced, utterly devoid velium on which the outline is traced, utterly devoid of transparency. Body colours for these purposes are generally sold in the form of powder, and require to be mixed with a little gun-water. They can be made, however, by the mixture of any simple water-colour with flake-white or Chinese white; thus, the heraldic colour is the statement in which will transpare to colour, blue with flake-white or Chinese white; thus, the heraldic name is obtained by mixing ultramarine or cobait-blue with either of these pigments. Body colours prepared in this manner are used by painters to produce bril-lisht effects in water-colour drawings, and form high lights, such as those reflected from armour, which cannot be obtained so clearly by putting on the co-louring shade by shade, or by wiping out with rag or

chamos leather.

BODY OF A CHURCH, the name usually given to the nate of a church, as distinct from the side-aisles and chancel. (See Navr.)

# Bohemian Brethren

BGREERIA, be(r)-meer-i-a, in Bot, a gen; of places belonging to the nat, ord, Urflences. From several species valuable fibres are obtained. B. frutescess, or puya, a plant growing wild in Nepaul and Sikkini, it he source of the celebrated Poosh fibre, which rivals the source of the celebrated Pooch fibre, which results the best European flax for tenacity. This species stains the height of six or cipit feet; but the steem is usually very slender. It is cut down for use when the seed is formed; the bark is then peeled off, dried, sold with wood-ashes, and beaten with mallets, to separate its component fibres. B. speciosa, the wild, rhea, also yields a very strong fibre, which is much used in the East. B. ninea, the Tehou Ma of the Chinese, is now known to yield the fibre used in the manufacture of the beautiful fabric called Chinese grass-cloth. The species of continuing this genus were formerly regarded as species of Urtica, the nettie.

BOREHAAVIA, bety-hat-ria (so named after Boer-

BORHHAYIA,  $be(r).hu!\cdot ij\cdot a$  (so named after Boerhaave, the celebrated physician), in Bot., a gen. of plants belonging to the nat. ord. Nyctoginacca. The species ere employed medicinally, both in Peru and the East Indies, having emetic and purgative proper-ties. B. tuberosa, a native of Peru, is employed as a

culinary vegetable.

Bog, bog (Celtic, soft), the name commonly given to a wet spongy morass, composed, for the most part, of decayed vegetable matter. The Bog of Allen is the most extensive of the numerous bogs found in the British isles. Chatmoss, in Lancashire, is another celebrated bog, being twelve square miles in extent. The origin and composition of bogs will be found to be fully treated of under the head PEAT.

HOG-BEAN. (See MENYANTHES.)

BOG-HEAD MINERAL, also known as the Torbane-head mineral (which see).

Bog IRON-ORE, a ferruginous deposit found at the bottom of bogs. It consists mainly of peroxide of iron, and is formed by the subsidence of the iron oxides and carbonates held in solution by the bog water. It occurs in some parts of America in such large quantities as to be commercially valuable. It is of a reddish-brown colour, and has been occasionally used as a pigment. Some varieties of bog iron-ore contain phosphates.

BOGNOR BEDS. (See LONDON CLAY.)

Bog-Oak, Bog-woon, a name applied to the trunks and large branches of cake, firs, and other trees found in the Irish and Scotch bogs. It derives its intense black colour from being impregnated with iron. It is very hard, and is capable of receiving a high polish. It is much used in Ireland, in combination with gold

and silver, for articles of jewellery.

Bogonitt, bog-om'-i-le, in Eccl. Hist., was the name of a sect which appeared in the 12th century, founded Basil, who was burned by Alexius Compenus in 1118. The name is derived from the Bulgarian bog, lord, and milui, have mercy. Their creed resembled the doctrines of the ancient Gnostics and Manicheans. They believed in two principles in the universe, a good and an evil; that the soul or spirit emanated from the good principle, but that the body and all material things were created by the evil one. Hence, they riewed the body as the prison-house of the immortal spirit, and believed that it ought to be energated by fasting, contemplation, and other exercises, so that the soul might gradually be restored to its primitive liberty. They were also opposed to marriage. They denied the reality of Christ's body, and rejected the law of Moses. They used no prayer but the Lord's Prayer, and rejected all sacraments. This sect was subjected to great persecution, but continued to exist down to the 13th century. Bog-TROTTER, a term of contempt frequently applied

to the lower classes of the Irish agricultural labourers, and founded on the singular ability they have acquired, by long custom and practice, of passing securely over the extensive quagmires or bogs of their native country. Where strangers would sink and sometimes perish in the treacherous morass, their habits and instincts teach them to find a safe footing,—a facility which formerly was often employed to clude the pursuit of soldiers, police, and officers of law.

ponce, and omeers of his.

BOHEMLAN, OF MORAVIAN SRETHERN, bo-he'-mi-an;
a sect of Christians, so called from the countries in
which they originally existed, but who designate themselves "The Union of Brethren" (Unitas Fratram).

They scose in Frague, the capital of Bohamis, about the middle of the 18th century, and were formed of certain remands of the Bussites who differed from the Calintines, another party of Hussites, in being more opposed to the errors of popery, and of stricter ecclemantical discipline. In 1453 they betook themselves to the borders of Silesia and Moravis, where they formed themselves into separate communities, and distinguished themselves from the rest of the Hussites by the name of Repthers of the Law of Christ the by the name of Brothers of the Law of Christ, the Union of Brethren, or United Brethren. They sufthere great persecutions, both from the Calixines and the Roman Catholics; but they suffered unresistingly, approxing nothing but reasonable remonstrances and presper to the rage of their persecutors. They were often confounded by their opponents with the Waldenses and Picards, and, on account of their being fre-quently compelled to conceal themselves in caverns and solitary places, they were called Cave-dwellers (Gradenkeimer). In spite of persecution, however, from the steadfastness of their faith and the purity of their morals, their numbers greatly increased, and in 1500 they numbered 200 parishes, most of whom had chapels connected with them. It being against their principles to engage in strife, they refused to take up arms in the Smalcaldic war against the Protestants, and, in consequence, Ferdinand deprived them of their churches; and in 1548 about 1,000 of them retired into Poland and Prussia, where they at first settled at Marienwarder. The agreement which these exiles entered into at Sentomir with the Polish reformers in 1570, and, still more, the Dissenters' Peace Act of the Marienwerder. Polish Convention in 1572, secured them toleration in Sales Convention in 137, secured them toleration in that country; while the subsequent persecutions of Sigismund III. united them still more closely to the Reformers, with whom they have maintained a connection to the present day. Those who remained in Moravia and Bohemis obtained some degree of liberty under Maximilian II., and had their chief seat at Fulmek, in Moravia. The Thirty Years' War, which terminated so disastrously for the Protestant cause, occasioned the entire destruction of the Bohemian churches and broke up their societies. Their last bishop, Amos Comenius, took refuge in England, and commended the cause of his people to their pious brethren of the Church of England. About this period, some of the persecuted refugees obtained pro-tection and privileges from the English government, and the church of Austin Friers, in the centre of London, was granted to one of their ministers. Again, in the reigns of Charles II. and George I., the case of these aufferers was recommended to the people of England, and moneys collected for their aid in the churches throughout the kingdom, with the express Those that remained in their own country continued to meet secretly and by stealth, until, at last, a number of them found refuge on the estates of Count Zinzen-dorf, in Lusatia, where they built an humble village, and assued it *Herrnhut* (the Lord's shelter), and which is still the principal settlement of the society. They first appeared as a body in England shortly before the middle of the last century. They laid their case before parliament, when their doctrines, discipline, and hisparliament, when their soctrines, uncupaire, and actory were scrapulously investigated by committees of both houses; and two bills were passed (20 Geo. II. c. 44, and 22 Geo. II. c. 30) in 1747 and 1749, exempting them from taking oaths and bearing arms in certain cases. The early Brethren attempted to restore of the Christian church, and the primitive purity of the Christian church, and framed their constitution according to the accounts They took the that remain of the Apostolic churches. Scriptures as the ground of their doctrines, and exercised a strict system of superintendence over their members, extending even to the minute details of domembers, extending even to the minute details of do-mestic life. For that purpose, they had a number of officers of different degrees,—viz. ordaining bishops, senses, sadies, and conseniors, presbyters or preachers, des-cesses, sadies, and scotytes,—among whom the manage-ment of the ecclesisatical, moral, and civil affairs of the community was distributed. They had three classes of members,—Myinners, proficients, and the refect, and three degrees of excommunication, and mber of emigrants from Bohemis and Moravia to

Herrnhut had considerably increased, and when many religiously disposed persons from other quarters came to settle among them, the consequent diversity of sextiments suggested the propriety of their having some rules drawn up for their direction and guidance cordingly, with the assistance of Count Zinas (who is justly considered to have been in some measure the founder of that society, to which he devoted his life, property, and energy), certain articles of union were drawn up, which, leaving all the distinctive doc-trines of the various Protestant denominations entirely out of the question, adopted, as articles of faith, only those fundamental Scripture truths on which they all agreed, and, at the same time, introduced a system of social compact and church discipline resembling that of the ancient church of Bohemian Brethren. articles were, after mature deliberation, adopted by all the inhabitants of Herrnhut, who pledged themselves mutually to their observance, under the name of a Brotherly Agreement, in 1727. They admit among them individuals from all Protestant denominations, without renouncing their original church or creed. In fact, they strenuously object to being considered a separate sect or denomination, maintaining that their union is founded exclusively on general Christian doctrines, and that their peculiarities relate solely to their social organization, by which they attempt to put truly Christian principles of life and conduct into actual practice. They profess a general adherence to the Angaburg Confession, but avoid discretions respective the proposition of the profession of the conductive of the profession of the pro general statements to the Augusturg Contession, but avoid discussions respecting the speculative doc-trines of Christianity. At a general synod held at Barby in 1775, it was agreed that they steadisstly maintain the following five points, without lessening the importance of any other article of the Christian faith :- 1. The doctrine of the universal depravity of man, and that, since the fall, he has no power whatever left to help himself. 2. The doctrine of the divinity of Christ. 3. The doctrine of the atonement and satis-Christ. 3. The doctrine of the atonement and satisfaction made for us by Jesus Christ; and that by his merits alone we receive freely the forgiveness of sin and sanctification in soul and body. 4. The doctrine of the Holy Spirit and the operation of his grace; that it is he who worketh in us conviction of sin, faith in Jesus, and pureness in heart. 5. The doctrine of the fruits of faith; that faith must evidence itself by willing obedience to the commandments of God, from love and gratitude. Their church is episcopal in form, and they have three orders of ciergy, bishops, prea-byters, and descons. The bishops alone are authorized to ordain ministers; but they possess no authority in the government of the church, except such as they derive from some other office. The presbyters are the derive from some other office. The presbyters are ordained stated munisters of the communities. degree of deacon is the first bestowed upon young ministers and missionaries, by which they are author ized to administer the sacraments. It is a general principle of the society, that their social organization is in no case to interfere with their duties as citizens and subjects of the governments under which they live, Where they form separate communities, they do not allow the permanent residence of any persons as house holders who are not members in full communion, and who have not signed the Brotherly Agreement; but they freely admit to temporary residence among them of such persons as are willing to conform to their external regulations. According to these, all kinds of amusements considered dangerous to strict morality are forbidden -as balls, duncing, plays, gambling of any kind, and all promiscuous assemblies of the youth of both sexes. In the continental communities to which unmarried u and boys not belonging to the families of the community resort, in order to prepare themselves for missionary or other labours, these reside under the care of an elder of their own class, in a building called the Single Brethren's house, where usually divers trades and manufactures are carried on for the benefit of the house or community; for it is a general rule with them that every member of the society devote himself to some useful occupation. A similar house, under the guidance of a female superintendent, is called the Single Sisters. house; and in larger communities there are also similar houses for widows who may wish to live aretired. Badd division of sex and station is placed under the special guidance of elders of their own description, who

# Bohemien Language

province it is to assist them with good advice and admonition, and to attend to their general interests. There are also special elders charged with the education of the young, as well as with attending to the spiritual attending to the s welfare of the married people. All these elders of both somes, together with the stated minister and the persons to whom the economical concerns of the community are intrusted, form together the board of elders, in whom rests the government of the community, with the concurrence of the committee elected by the inthe concurrence of the committee elected by the in-babitants for all temporal concerns. This committee superintends the observance of all regulations, has charge of the police, and decides differences between individuals. Matters of general interest are submitted to a meeting of the whole community. The female elders, though they attend the board of elders, have no vote in their deliberations. The most distinguishing feature of this body is their carnest and unremisely effects the diffuse a knowledge of Christianity to the efforts to diffuse a knowledge of Christianity to the most remote and neglected portions of the globe. It is this that has more particularly gained them the esteem of so many great and good men. "Who," says Dr. Chalmers, in reviewing the good that had been effected by their means, "would not long to be in possession the charm by which they have wrought this wonderful transformation,—who would not willingly exchange for it all the parade of human eloquence, and all the confidence of human argument." In 1851 the number of their chapels in England and Wales was 32, with 9,305 sittings. Though the entire number of members in that year did not exceed 12,000 in Europe, nor 6,000 in America, they had 294 missionaries and 70 settlements distributed among the Hottentots, Greenlanders. Requirement land, australian aborigines, and the negroes of the West Indies and America. The number of converts belonging to the missionary congregations was about 70,000. The annual expense of carrytions was about 70,000. The annual expense of carrying on this great work is only about £13,000, three-fourths of which are raised by other Christian bodies (principally by the Church of Eugland), who appreciate the value of their labours.

BOHEMIAN LANGUAGE AND LITREATURE. — The Bohemian language, termed by the people themselves the Czechish, is a branch of the Slavonic, and is spoken by about 7,000,000 of persons in Bohemia, Moravia, and Upper Hungary. It is one of the best dialects of the West Slavonic, and is distinguished from its sister dialects by the number of its roots, its great flexibility, precision of expression, and elegant grammatical con-struction. Like all the Slavono tongues, however, it wants a proper form of the passive voice. It is the most powerful and manly, but at the same time the hardmost powerful and manny, out at the same time the nare-est of the Shavonic hanguages. It is also distinguished by its precise and regular orthography, introduced in the 15th century by John Huss, in which, by the use of the Roman alphabet, every sound has a particular character assigned to it. What, however, chiefly dis-tinguishes it from most of the other European languages is, that here, as in the aucient tongues, the quantity prevails, while in the modern tongues it is the accent that governs. It is thus particularly well adapted to represent the various kinds of Greek and Latin metres. No other tongue can so completely and forcibly, and yet so naturally, convey the meaning of the ancient classics in translation as the Bohemian. Its grammar is more difficult to master than that of most other European languages, on account of its complicated forms and construction. The Bohemian literature is older than that of any of the other Slavonic tongues, ascending at least as early as the 10th century. Of the carliest period of its history, or that preceding the time of John Huss, several remains still exist. In 1917, Mr. Hanks, keeper of the National Museum, discovered at Königinhof part of a collection of epic and lyric poems of the 13th century, which are said to be characterized bygreat power, feeling, and tenderness. There remain, besides, of this period, about twenty poetical, and over Tensues, or anis period, about swenty poetical, and over fifty prices works, great or small. Among these are, Dalimil's "Bohemian Chronicle," in verse (1814); Thomas of Stiny's "Lehrbuch für seine Kinder" (1876); the still popular fable of the "Council of the Beasts; "Andrew of Dubs's work on the Judicial Council of the stitution of Bohemia (1402); and the comedy of the "Mountebank" (Quacksalber), about the beginning of the 14th century. John Huss, like Martin Luther, was

# Bohamien Langua

s reformer in language as well as in religion, and his time dates a new period of Bohemian Ricersis (1409—1526). He revised and improved the Bohemia translation of the Bible, and was the author of sea twenty books besides. Yet his influence on the likest ture arose less by what he wrote than by the vigo which he imparted to it. In the old libraries as archives lie, unknown and disregarded, almost innum rable tracts and treatises, dogmatic, polemical, and ascetical, by the different sects of Hussies of the 15th century. Poetry sank almost to mere rhyme, thaugh saccutars, by the different sects of Hussies of the tisting century. Poetry sank almost to mere rhyme, thrugh some of the church hymns of the Hussies are not without poetical merit. The prose, however, of this period became more fixed and expressive and was the only medium of all public transactions. The tistic papers, as well as the correspondence of the sistemen this period, are excellent specimens of a curt, clear, se, and expressive style. It is particularly rich in terse, and expressive style. It is particularly rich in national works; and of the historical works of this period, a number have been edited by Palacky in his Ser riod, a number have been edited by Falacky in his Scriptores Rerum Bohemicorum (1829). The period from 1526 to 1620 is called by the Bohemians the golden age of their literature. During it, particularly under the reign of Rudolph II. (1576—1611), all the aciences and arts were studied with diligence, and an attachment to the same was publicly manifested by all classes of society. Education was much attended to, and in Prague alone Education was much attended to, and in Frague alone there were two universities and sixteen other seminaries of education, among which were several girls'-schools; while throughout the country there were numerous gymnasiums and parish schools. The language reached its highest point, both grammatically and socially; and the number of works of every kind and obaracter that appeared during this period is very remarkable. Yet it cannot be said that the works of this time display any great amount of originality or genius. The fourth period begins with 1620 and ends with 1774, when, after the battle of the White Mountain, the whole Bokemian nation submitted to the conqueror. Perhaps never did the battle of the vinite mountain, are when a mation submitted to the conqueror. Perhaps never did a people so speedily fall from a high state of cultivation back to the deepest barbariam. The leading men of a people so speedily latt from a night state of curvessors back to the deepest barbarism. The leading men of the nation mostly perished by the sword; the clergy, scholars, nobility, and in general all the more cuttivated part of the nation, left the country. Their places were supplied by Italian, Dutch, Spanish, General and the nation, the nation, the country of the nation, the nation, the nation of the nation, and the nation of the man, and other adventurers, who came in troops, and possessed themselves of all dignities and offices. Jesuit missionaries went from place to place and house to house, accompanied by soldiers, in order to take and nouse, accompanied by somers, no root to take and destroy all hooks suspected of heresy. This unfortante destruction of books was continued far into the 18th century; and even so late as 1750 tho Jesuit Antony Konias boasted that he had destroyed 60,000 Bohenian books. It is therefore matter of wonder that we still possess so much as we do of the ancient that we still possess so much as we do of the sacismat literature. In the early part of this period these were still some writers who, indebted for their culture to the previous period, continued to shed a kind of light on this deep darkness; and many of them published works in Amsterdam, Berlin, Dreaden, and other places, and sent them to Bohemia. One of the last of these bright stars was Johann Amos Comenius, the last bishop of the Bohemian Brethren, and who is still known as a writer on education. In 1774 an imperial decree ordered the establishment of German schools—are all high and elementary, throughout Bohemia. normal, high, and elementary—throughout Bohemia; and in 1784 it was decreed, that in the higher schools instruction should only be given in German; so that one could only obtain the elements of learning in his mother tongue. This, which seemed to be a death-blow to the language, had in reality a contrary effect. It stirred to new life the alumbering energies of patriotic men in behalf of their mother tongue. General Count Francis Kinsky and the historian Pelzel were among the first to come forward and vindicate the claims of the unfortunate language; and they at length succeeded in obtaining some slight modifications of the decree, so that in the higher military schools instruction might be given in the Bohemian tongue. A number of the state of th ber of distinguished writers also arose, who made use of this language; as Pelzel the historian, whose work "Nowa Kronyka Czeska" (1791-96) is one of the best nowa Kronyka Czeska" (1781-96) is one of the best handbooks of Bohemian history; the monk F. F. Prochaska, Wenzel M. Kramerius, Dobrowsky, and others. The labours of these individuals at length led.

307

# Bohemian Warwing

to an improvement in the state of matters; and in 1613 a decree was issued recommending the pas of the Boltonian language in the gymnasiums. Since that time a love of the old dialect has been rapidly extend-ing, and a knowledge of it has been diffused through ing, and a knowledge of it has been diffused through all classes of society. In poetry and belles-lettres, among the names that have recently arisen are Czelakowsky, Kollar, Holly, Lauger, Schneider, and others; in philology, Jungmann, Schafarik, Hanka, and Frest; in history, Palacky and Tomek; in archæology, Schafarik and Wooel; in geography, Schadek and Zap; in physics, technology, &c., Sedlakzek, Smetana, Ameriling, and others. Since 1831 there has been, in connection with the Bohemian museum at Prague, a special committee for the cultivation of Bohemian literature, numbering in 1849 4,000 members. It has aided in the publication, among other works, of Schafarik's "Slaronic Antiquities," and Jungmann's "Lexicon" and his "History of Literature." In 1851 there were published twenty-two Bohemia, five in Moravia, four in Hungary, and two at Vienna. Ref. Brockhaus Conversations Lexikon.

Bourman Waxwing, cair'-wing (Bombycicora garrale), a bird which is a winter visitant to Britain. The country in which the young are reared is not known

country in which the young are reared is not known with certainty. M. Temminck, however, states that the European waxwing breeds in the eastern part of the north of Europe, and lives in the northern parts The waxwing is about the size of the starling, of Asia. The waxwing is about the size of the starring, and is distinguished more for its pretty plumage and

graceful form than for superior vocalization.

Boil, boil, called also furunculus, from the Latin furo, I rage, on account of the violent heat and infismmation attending it, is a hard painful tumour of the skin and the subjacent cellular tissue. It makes its appearance as a small hard inflamed spot on the skin, and gradually enlarges into a painful tumour, having a white conical centre, surrounded by a hard inflamed base, and varying in size from the bulk of a pea to that of a pigeon's egg. It proceeds to suppuration, and discharges a few drops of purulent matter commonly mixed with blood, and a central mass called commonly mixed with blood, and a central mass called the core. This last often lies deep, and causes con-siderable pain before coming away; but, without its removal, the abscess will not heal. Boils, though generally very troublesome, are not attended with danger. They occur mostly in young and vigorous persons; but they also occasionally break out upon the weak and deficate. They sometimes flow each other in rapid succession, and are most common in the apring. They all take their rise in some disordered state of the digestive organs; and the need to more disordered state of the digestive organs; and hence it is necessary that the bowels be at first freely opened, and then regulated by gentle unirritating laxatives. The diet should be plain and simple, and stimulants ought to be avoided. In delicate constitutions a course of sarshould be plain and simple, and stimulants ought to be avoided. In delicate constitutions a course of sar-saparills will be found of great use. In dealing with the boil itself, suppuration is to be hastened and per-fected by means of linseed-meal poultices; and as soon as the prominent part of the swelling becomes soft, a free opening should be made into it with a lancet, and as much matter as can be pressed out of it by tolerably firm pressure should be removed, together with the core; or the poultices should be continued until the core is drawn out, when the wound will speedily heal.

Boller, boil-er, a name applied to vessels in which water or other fluids are exposed to heat, for the purpose of exporation, or for the formation of steam.

Small boilers are mostly made of copper; larger ones of the best wrought iron. They are of various shapes, being generally constructed so as to obtain the largest heating surface with the smallest cubical contents. (See STEAM-ENGINE, LOCOMOTIVE, SUGAR-REFIRING.) By the continual evaporation of the water in steam boilers, the saline matter contained in it, at last becomes so concentrated, as to form a deposit open the sides and bottom. In many instances, especially when the water used is greasy, this deposit has been the cause of explosions, from covering the iron so tightly as to allow it to become red hot all through.

# Boiling-points

the purpose of preventing the formation of these incrustations. The addition of chloride of ammonium to the water in the boiler, as proposed by M. Ritter-brandt, is very effectual. The chlorine combines with the lime, and the carbonic scid with the ammonis, forming chloride of calcium and carbonate of summonis, two very soluble salts. Chloride of tin and alkaline carbonates are also used for this purpose.

Boiling-points, boil-ing points.—A liquid is said to

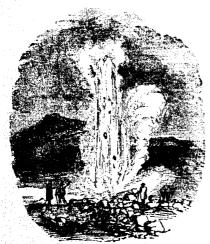

boil when it is made to assume a constant state of chullition by the formation of bubbles of its vapour by means of heat. The boiling-points of liquids differ seconding to their chemical constitution; in many instances, in direct ratio to the differences in their composition. The boiling-point of the same liquid may vary under different circumstances; such as the pressure on its surface, the amount of attraction exerted by the vessel containing it, or by salts held by it in solution. Boiling, or the emission of steam in bubbles, consists in the formation of a vapour of equal elasticity to that of the atmosphere, which exerts its pressure on the surface of the liquid. It therefore follows, that any lessening or increasing of the pressure of the air is accompanied by a corresponding depression or elevation of the boiling-point. This fact is made evident by the familiar experiment of placing warm water under the receiver of an air-pump, when, on exhausting the air, ebullition takes place, from the diminished pressure. Liquids, in general, boil from 60° to 140° lower than their ordipary boiling-point when heated in vacuo. This property is made use of in the manufacture of certain medicinal preparations, the properties of which would be destroyed by exposure to a temperature of 212°. Advantage has been taken of this property of fluids in the measurement of heights. M. Saussure found that on the summit of Mont Blanc, which is nearly three miles above the level of the sea, water boiled at 185° Fah.; and M. Wisse observed the boiling-point of water to be 1850 Fah. on Mount Pechinchs, while the barometer stood at 17 inches. From these facts it has been calculated that for every difference in height of 596 feet, a variation of 1° Fah. in the boiling-point is produced. It has also been ascertained that a variation of one-tenth of an inch in the barometer produces a difference of more than a twentieth of a degree Fah, in the holling-point. The contrary property of increase of pressure causing elevation of the boilingpoint, is evident from the above considerations. Pa-pin's digester is an example of this. By confining water in an air-tight vessel, it may be heated to a temwater in an air-light vessel, it may be nested to a tem-perature only limited by the strength of the vessel. This property is taken advantage of in the preparation of gelatine from bones, which are heated to a tempera-ture much higher than 212° Fah. By this means the gelatine is easily separated from the earthy matter, although the bones might be boiled for hours at 212° Fah. without any such effect taking place. The attraction of a fluid for the surface of the vessel in which water boils at 212° in a metallic vessel, in a glass vessel at 214°, while in a vessel varnished inside with shell-lac the heat may be raised to 2200 without chul-lition taking place. The influence of salts held in solution is very marked. A saturated solution of chlorate of potash, i. c. containing 01 5 per cent. of the sait, boils at 220° Fab.; a saturated solution of chloride of calcium, containing 325 per cent. of the salt, boils at 355° Fah., while a saturated solution of acetate of potash, containing 798 per cent. of the salt, botle at 336° Fah. It will be seen from these examples that the quantity of salt contained in the liquid does not directly influence the boiling-point. From the experiments of Kopp and others, it has been discovered that an exact ratio exists between the chemical constitution of certain liquids and their boiling-points at the same pressure. Thus methylic, ethylic, propylic, and butylic alcohols differ from each other by an increment of CaH2, and their boiling-points differ by an increment of 31.4° Falt. Another example of this is shown in the hydrocarbons benzole, toluole, xylole, and ex-mole, the difference in their composition being C.H. so against as to allow it to become red hot all through. I mole, the difference in their composition being C.H...

BOILING SPHINGS, OF GRYSERS, the name given to sertain springs in Iceland, where boiling water is

## Bollar dists

it a nearly circular basin, upwards of fifty feet in diameter, it slopes towards the centre like a samer, and has an average depth of five feet. In the middle is a cylindrical passage, about seventy feet deep and twelve feet in diameter, up which the boiling water rises and the eruptions burst forth. These eruptions rises and the eruptions nurst form. These crapsome cocur at periodical intervals, and are proceeded by a loud report like that of artillery. Sir John Stanley, in describing this spring, says that the water in the basis was first violently agitated, and the ground shaken; the air was then filled with volumes of steam, rolling over each other as they ascended in a manner inex-pressibly beautiful, through which columns of water, shivering into foam, darted in rapid succession to the height of nearly 100 feet. It has been ascertained that neight of nearly 100 feet. It has been ascertained that the boiling springs of Iceland have been playing for the last 600 years; but very material changes have taken place from time to time amongst them. They have doubtless a connection with the volcances which abound in the island; and their temperature varies from 188° to 212° Fahrenheit. The inhabitants of Iceland use them for bathing when their position suits and also for boiling fish, evaporating sea-water, and such-like purposes.

BOLDERBERG BEDS, boll-der-bairy, in Geol., a typ cal group of tertiary sands and gravels occurring in the Bolderberg hill, about 40 miles from Brussels.

Bole, Armenian, bole (Swed. bol), a dark-red hydrated silicate of alumina, mixed with peroxide of iron in large quantities. It also contains traces of hime and magnesis. It is occasionally used for coarse paint and for stage purposes. When the amount of mag-nesia is such as to cause it to feel greasy, it is termed

mountain scap, or fett-bol.

Bour, in Geol., a term sometimes applied to any friable clayer shale or earth coloured red or brown by

peroxide of iron. Bolero, bo-lair'-o (Span.), a Spanish national dance, usually accompanied with the castanets and the cithers, and sometimes with the voice. The dance is intended and anometimes with the commencing with corporate and diffidence, and gradually rising to the expression of passionate cestasy. It is in the time of a minuet, and has a marked and singular rhythm.

Bolerus, hole-tus, in Bot., a gen of fungi, which may be distinguished from Agaricus by the absence of gills, the under-side of the cap or pilous being covered by a porous layer composed of innumerable short tubes united together. Some of the species are edible, though they are all set down as mere toadstools by the mushroom-gatherers of this country. B. edulis, the Ceps ordinaire of the French markets, is much used throughout the European continent. It grows in woody situations and attains a considerable size, the cap being usually six or seven inches across. The colour of the cap ranges from light brown to brownish-black, white that of the layer of tubes beneath is at first white, then yellow, and finally yellowish-green. The stem is thick, solid, and beautifully reticulated. To prepare the fungus for the table, the layer of tubes, the skin, and the stem, must be thrown away, for nothing but the firm and delicate flesh of the cap is to be eaten. This may be either caten raw with salt and pepper, or cooked like a common mushroom. Many other species are usually found exposed for sale in the French markets.

BOLLANDISTS, boll-lind-ists, a society of Jesuits at Antwerp, who are celebrated from having undertaken the publication of a work entitled "Acta Sanctorum," which was to give all that was known concerning the saints of the Roman Catholic church. The work was projected by Heribert Rosweyde, but he died before projected by Heribert Rosweyde, but he died before any part of it was ready for the press, and was succeeded by John Boliand, who gave his name to the society, and by whom the two first volumes (for January) were published in 1643. The three for February appeared in 1653, and the three for March in 1668. In consequence of the suppression of the order of Jesuits in 1773, this society removed to the Augustine abbey of Caudenberg, at Brussels, where it continued till the accession of Joseph II., which led to small plain, sixteen miles north of the willage of Skalholt. The street of the Great Geyser have formed for S00 feet high and 10 feet in diameter. The silicious deposits of the Great Geyser have formed for 300

### Bollards

# Bolognese School of Painting

(1784) when the French accupation put an end to their labours. In 1837 a new Bolkendist association of Jesuits was instituted by the Belgic government, which act maids an animal sum of 6,000 frames for carrying on the work; and in 1845 the 54th volume appeared. Since that time two more volumes have been published, the last in 1858, bringing the work down to the 22nd of October; and, when finished, it is expected to occupy 70 large follo volumes. It was estimated that the 53 volumes published before the French revolution consin upwards of 25,000 lives of saints. From being sarried on by so many different hands, the work is of vary unequal merit, and though abounding in legends and absundities, they contain much valuable historical information, and the documentary evidence is often new above and on the documentary evidence is often

The salty and honestly criticised.

\*\*BOLLAMOS, bol'-tards (Ang.-Sux.), in Mar., are large posses sunk in the ground on each side of a dock. On socking or undocking ships, large blocks are fastened to them, through which are passed the transporting hawsers to be brought to the capstans.

BOLOGNA PROSPHORUS, bo-lone'-ya.—Sulphate of baryts on being ignited with a small portion of carbon, and exposed to the sun's rays, acquires phosphorescent properties, and is called Bologna phosphorus, from having been first discovered in that city. The explanation

nation of this phenomenon is not very clear.

BOLOGNESE SCHOOL OF PAINTING, bo-lone'-yes-ze. \* resemblance in style and manner among painters who have become masters of their art in any locality, during a series of ages, whose works present a similarity of treatment, not arising from a deficiency of original ideas, but from the influence of situation and general ociations, and the example of great minds that have a to a point considerably above the level of those who have gone before them, who have thus contributed to establish a higher degree of excellence, which is worthily imitated and adopted by their followers and beesors. But merely considering the term to point est the associated names of a certain number of painters of selebrity, who either claim a town renowned for the production of brilliant works of pictorial art for their birthplace, or, coming from elsewhere, have settled and wrought there, associating their names inseparably th the place which they have chosen as the scene of sir studies and labours,—whose various productions, ressons above stated, have become imbued with a milarity of style, feeling, and expression,—it will milestly be requisite only, in the present article, to size briefly at the various masters who adorned the Beloguese school in successive centuries, pointing out their progress towards excellence, by a judicious selection and adoption of the most meritorious points in the odnotions and styles of eminent masters of other hools, and the time at which the highest degree of rection was attained. In the 14th century, Franco f Belogna, called the Giotto of the Bolognese school, Stained a high reputation as an illuminator of missals. He also painted pictures of some considerable size, someder of the school of his own ers, with whose style and spirit the works of his contemporaries and sucsessors became deeply imbued. Specimens of their works still exist in the church di Mezzarata. At the commencement of the 15th century, Lippo Dalmasio, whose chief subject was the Virgin, from which prediction he is known as Lippo delle Madonne, or Lippo of the Madonnes, attained a reputation for the expression of piety, combined with grandeur of treatment, that he threw into his works, caused, most probably, by the influence which the Byzantine school of art exercised over the early Italian painters. (See By-SANTINE SCULPTURE.) An attempt made subsequently to introduce the style of treatment adopted by Venetian stists, by Marco Zoppo, who painted between 1470 and 1500, seems to have failed; and the name of Francesso Francia, a contemporary of Rafaelle, whose bistory bears certain points of similarity to that of in Matsys, as both were originally artificers in metals, and adopted painting as a profession in after-life, closes the century as the most celebrated of his school, famous for the boly and pure expression of countemance given to his Madonius; he has been and by some writers, though improperly, with con-

temporary painters who reached for greater emineuses in other schools. The next painters of reputation in the Bologness colool who flourished in the 16th contary, were Ramenghi (named Bagnacavallo), Innocense da Imola, Primaticcio, and Pellegrino Tibaldi. The first of bless introduced. of these introduced an imitation of the style of Refaelle into his works, which was copied by his pupils; while the last-named, after passing his early years in the studio of Bagnacavallo, studied under Michael Angelo at Rome, and infused much of the spirit of this wonderful painter and sculptor into his works. But the ex-cellence of the Bolognese school, that had hitherto only sought to combine the successful modes of treat-ment adopted by Rafaelle, Michael Angelo, and other ment adopted by Kanene, Attended Angelo, and cater artists of eminence, in a manner approaching servility and mere superficial mannerism, was shortly to reach its culminating point in the productions of Ludovico Caracci (see Caracci et al. of this work), and his cousins, Agostino and Annibale, as well as in those of their scholars and contemporaries, Guido and Domenichino, who had previously studied under Dermit Calchino, who had previously studied under Dermit Calchino. chino, who had previously studied under Denis Cal-vart, a painter of Antwerp, who had settled in Bologna, and had introduced a taste for landscape-painting, which exercised a manifest effect on the works of the painters that have just been mentioned. Ladovico Caracci, who seems to have been influenced in a great degree by the paintings of Correggio, regarded at that time by all existing schools as a model of excellence well worthy of imitation, after studying at Venice and Parma, determined on the introduction of a new style, in which his cousins were persuaded to assist. The chief characteristics of this new element in the Bolognese school seem to have been a careful observation of nature and natural effects in conjunction with the imitation of the various styles of the great masters, and a proper attention to correct outline-drawing, perspec-tive, and the anatomy of the human figure, which had been neglected by the predecessors of the Caracci. An impulse in a fresh direction was thus given to the art of painting, and the labours of Ludovico at Bologna, and of Annibale at Rome (the best exemplification of whose powers as an artist, and of the peculiar characteristics of the Caracci school, is to be found in the Farness palace, in a series of frescoes), imparted a new colour-ing, and exercised a decided influence over works of art produced about 1600, and for many years subsequently, throughout Italy. The leading features of Ludovico Caracci's paintings, as given by Sir Joshua Reynolds, are—great breadth of light and shadow; simplicity of colouring, which has the merit of not drawing away the attention of the spectator from the subject of the painting; and a ruellow wilight effect that seems to be diffused over his pictures, and is in perfect harmony with the grave and dignified subjects which he close for treatment. Domenichno was brought into notice by Poussin and Annibale Caracci, though this painter, as well as his cousin Ludovico, was jealous of the superior talents of his pupil Guido, who combined the dark peculiar style of Caravaggio with that of his former masters, but afterwards adop a lighter and more lustrous tone which pervades his productions. Among other followers of the Caresci and painters of the Bolognese school may be enumerated Guercino, Lanfranco, Tiarini, Lionello Spada, and Cavedone. Since the middle of the 17th century no painter of eminence has been found in this school to sustain the reputation which had been acquired for it by the Caracci and their pupils, with the exception of Carlo Cignani, who was mainly instrumental in founding the Clementine Academy of Bologus, in which he sought to combine the study of the old masters with a careful observation of nature and attention to anatomical science. The following is a list of some of the tonical science. The following in late of season take paintings by Bolognese masters in the National Gallery, attording good examples of their different peculiarities of style and method of execution. Name of Artist. BOLSTER, bole'-ster (Sax.), a long cushion used for supporting the heads of persons lying in bed. In sad-diery, bolsters are hose parts of a saddle raised upon the bows or hinder part, to hold the thighs of the rider. In Mar., certain cushions or hags stuffed with tarred canvas are called bolsters. They are used to protect the stays from being chafed or worn by the motion of

the masts during the rolling of the ship at sea.

BOLT, bolte (Sax. bolt; Goth. bolte, a fetter).—In Mar., bolts are short cylindrical pieces of iron or copper, varying in diameter from half an inch to three inches, and of various lengths, used for securing the timbers of a ship to the ribs, and for fastening the knees, beams, and various parts of the vessel together. These bolts differ in form according to the purpose for which they are designed, and are distinguished by shipwrights according to the form of the head. The term wrights according to the form of the head. The term "bolt" is variously applied; a sliding bar of iron fitting into a socket to accure a door, and the short arrow with a weighty head discharged from a cross-bow, are An iron fetter is sometimes called a fetterbolt, particularly in Her.; and a piece of sailcloth twenty-eight ells in length is called a bolt of canvas

BOLTHEAD, bolt'-hed, a glass vessel consisting of a globe with a long narrow neck, used in chemical ope-

rations for boiling and subliming.

BOLT-Ropes, in Mar., the name applied to ropes
which are attached to the edge of a sail to prevent the canvas from splitting and tearing when there is a heavy strain upon it. That part which runs along the upper edge of the sail is called the head-rope, that along the lower edge the foot-rope, while that which is sewn to the edge on either side is termed the leech-rope.

Bolus, bo-lus (Gr. bolos, a mass), a large soft kind of pill, larger than a common pill, but yet not too large to be swallowed at once. It might be composed of any of the ingredients used for pills; but it was an incon-

venient form, and is now generally discarded.

Boun, bom (Gr. bombos, a loud noise), a very de structive missile used in warfare. It is usually in the form of a hollow sphere or shell, made of cast-iron, and illed with combustibles. There is a communication between the interior and exterior by a vent-hole, through which a fusee passes. When a bomb

is fired out of a mortar or gun, the fusee is lighted and burns slow-

ly, only reaching the interior powder as the bomb falls; the mass of metal then bursts,

BOYE.

the fragments working great havor as they fall amongst the enemy. Bombs were formerly only fired from mortars; but since the late improvements in artillery they have been much fired from guns and howitzers. The name of shell, or bomb-shell, is principally used to distinguish this kind of implement, notwithstanding the shape has changed in some cases from the sphere to the cylinder or

cylindrical cone. (See SHELL, ARMSTRONG GUN.) The Venetians claim the invention of the bomb as early as 1878; but it did not come into common use in warfare thi 1634, and then only between the Dutch and sanish armies. An English engineer named Malthus said to have first introduced bombs into France at enish armies. siege of Collioure in 1793.

Born beaut

After the cruel bombardmen Messina, in 1848, when so many lives were lost and much property destroyed, Francis II., king of Nam and Sicity, acceived the nickname of Bombs. His sen, who succeeded him, is sometimes called Bombslino. After considerable resistance, he was driven from his throne by Garibaldi and Victor Emmanual, who took the title of king of Italy.

BOMBLORE, bom-bai'se-e, in Bot., a group of plant now usually regarded as a tribe of the nat. ord. Size

now usually regarded as a tribe of the nat. ord. Marsiculiacea. It comprises several interesting general; namely, Adansonia, Bombax, Cheirostemon, Dario, Eriodeudron, and Ochroma, which are separately described in this work.

BOMBARDIER, bom-bar-deer, a non-commissioned officer in the artillery, corresponding in rank to a lance-corporal in the line, and distinguished by wearing one chevron on the left arm. In former times artillery-men so cutifled were especially employed in stilling shells and grandes, and preparing forces. filling shells and grenades, and preparing fusies, as well as in serving mortars and other pieces of ordnance from which shells are thrown during the siege of a town.

BOMBARDINE BERTLE, a name applied to many co-leopterous insects of the tribe Carabida. They are divided into two genera,—the Brackinus and the Ap-tinus; the latter has no membranous wings under the wing-sheath. Those found near the tropics are large and brilliantly coloured, but those found in this coun-try are generally small. They are called bombardies beetles on account of a remarkable property they possess of violently expelling from the anus a pungual acrid duid, which, if the species be large, has the power of producing discoloration of the skin, similar to of producing discoloration of the skin, similar to that produced by nitric acid. It also changes blac-vegetable colours to red, and then to yellow. The most common English species is little less than half an inch long: if irritated, it will make more than twelve rapid discharges. Each expulsion of the finid is accompanied by a very lond report, considering the size of the insect. The hombardier beetle is generally found under stones, and occurs plentifully in chalky, districts. districts.

BOMBARDMENT, bom-bard'-ment (Ital. bombarda-mento), the expression applied in Mil. to the ect of throwing red-bot shot, shells, and congreve rockets into a fortified town, to effect the destruction of powder-magazines, dockyards, warlies stores, buildings of a public character, and private dwelling houses. A bombardment is invariably attended with terrible destruction of human life and property, and is resorted to in order to induce the governor or officer in command. to save the inhabitants from death and ruin by capitulation. It finds little favour with military and naval men, on account of the misery with which such a process is attended to those who are not actually in arms against the attacking force; and is seldom put in practice unless the place cannot be reduced by a regular siege. During the siege of Sebastopol, in 1854-5, a furious bombardment of the town and defensive works was bombardment of the town and derenaive works was kept up for some days, at six successive periods of the fivestment, in the last of which, justly characterized by the Russian governor, in his dispatches to the em-peror, as a feu d'enfer, about 28,600 red-hot shot and shells, with other missiles, were hurled into the heart of the city and against the fortifications. Some idea of the expense attending a bombardment may be con-ceived from the fact that nearly 252,000 rounds of shot and shell were expended during the siege, besides those fired from the vessels surrounding the entrance to the harbour, which represents a mass of above 8,000 tons of iron, supposing each shot to average three-quarters of a hundredweight. Among the most famous bombardments mentioned in history, are those of Gibraltar, by the French and Spaniards, from 1779 to 1783; Havre, by Admiral Rodney, and Lille, by the Austrians, in 1793; Copenhagen, by Lord Nelson, in 1891, and again by Lord Catheart and Admiral Gambier, in 1807; and

Algiers, by Lord Exmouth, in 1816. BOMBAST, bom-bits', in Lit., is an attempt to raise an ordinary or trivial object to the rank of the sublime, or to exalt a sublime object beyond all natural or res sonable bounds,-

" My roof receives me not; 'tis air I trea And at each step I feel my advanced head. Knock out a star in heaven."—Ben Joneon. BOMESK, bom'-box, in Bot., a gen. of plants, the type of the tribe Bumbaces. The species are natives of South America and India, and are commonly known as silk-cotton trees, owing to their seeds being covered with long silky hairs. These hairs cannot be spun into thread, like those of ordinary cotton; but they are sometimes used for stuffing heds and cushions. The American tree B. Cellos, and the Indian tree B. pentandrum, are remarkable for their prodigious height. The bark of the latter is said to be emetic.

BOXBAZINE, bom'-bū-zeen (Gr. bombyx, a silkworm), is a woven fabric, the warp of which is silk and the weft wood. The manufacture was introduced at Norwich by some Dutch weavers, who settled there in 1575. Bombasine was at first made in different colours; but

of late years it is only used in deep mourning.

Bourse Acro, bom'-bik, an acid formed by silkworms, analogous to, and most likely identical with, that obtained from ants, and called formic scid. (See FORMIC ACID.)

BOMB-KETCH, a vessel built and strengthened with large beams, equipped with two masts, and fitted with all the conveniences and appliances for the use of morters at ses. These vessels are usually about 100 to 250 tous burden. (See MORTAR-VESSEL.)

BOME-PROOF, a term applied to military structures which are so constituted that any missile discharged from a gun, as a bomb-shell or cannon-ball, cannot penetrate them. Magazines are constructed bombproof, and are generally made very strong; and case-mates are bomb-proof vaults in fortresses, for the security of the defenders.

BOMBYX. (See SILEWORM.)

BONA FIDES, or BONA FIDE, bo'-na fi'-dees (Lat., good faith, or in good faith), an expression frequently used to denote a thing done with an honest intention, in opposition to one done with a bad or deceitful intention, said sition to one done with a bad or decentin intention, said to be malé fide. The phrase originated with the Romans, who classed under bonæ fidei obligations a great variety of contracts, as well as of legal acts. Actions bonæ fidei were distinguished from those stricti juris; the former having regard to the honesty of the intention, the latter to the strict legal terms of the deed. The distinction was somewhat analogous to that which prevails between courts of law and courts of equity in England.

BONA NOTABILIA.—Where a person dies, having, at the time of his death, goods in any other diocese be-sides his goods in the diocese in which he dies, amounting in value to £5 in the whole, he is said to have bona notabilia. They consist of simple-contract debts, specialties, judgments, leases of lands or houses, &c.

BONASSUS. (See RISON.)
BOND, bond (Sax. bond, bound or tied), in Arch., a term applied to certain methods of laying bricks (see BRICK-WORK), and to timbers built into or attached to the walls of a house for various purposes. Stones are called bond-stones when they are introduced longitudivally into a wall built of small rough stones or rubblework. Bond-heart, in building, is when one stone is placed in the centre of a thick wall, over the joint formed by two others, the outer faces of which appear opposite to each other on either side of the wall. Bond-timbers are pieces of wood let into the sides of openings for doors and windows, to which the windowframes, jambs, and architrave of the doors and architrave-mouldings, may be nailed, and the long slips of timber built into a wall in a horizontal direction, at intervals of eighteen inches or more, to which the battens are attached

BORD, or Writing Obligatory, a kind of contract in very extensive use, being adopted, in a great variety of cases, where the object is to obtain security for the payment of money, or the performance of any other set; being a deed, or instrument under seal, whereby a party from whom a security is intended to be taken, a party from whom a security is intended to be taken, obliges himself to pay a certain sum of money to another at a day specified. If this be all, the bond is saided, a single one (simplex obligatio); but there is generally, indeed in practice invariably, a condition added, that if the obliger does some particular act, the obligation shall be void, or, else, shall remain in full farre. The nature of this act depends upon the par-ticular object intended to be secured. Thus, it may be the repayment of a principal sum borrowed of the

obliges, with interest, the periodical payment to him of an annuity, the faithful performance, by a third party, of the duties of an office or employment under the obligee, the performance of covenants by the obli-gor, the indemnity of the obligee against loss, or the consequences of certain acts, and a variety of other matters; but whatever the nature of the act, the penalsum (or penalty) mentioned in the obligatory part of the bond becomes forfeited, or absolute in law, and charges the obligor, while living, and, after his death, his executor or administrator, and (subject to certain distinctions) is also capable of being enforced against his heir or devisee. If the coudition of a bond be impossible at the time of making it, or be uncertain or a possible at the condition along its said which are also as the condition of the condit insensible, the condition alone is void, and the bond shall stand single and unconditional; for it is the folly of the obliger to enter into such an obligation, from which he can never be released. But if the condition be to do a thing which is either illegal at common law, or contrary to the provision of an act of parliament the whole bond is void; for the whole is an unlawful contract, and the obligee shall take no advantage of such a transaction. If the condition, at the time when the bond is executed, be possible and legal, and after-wards becomes impossible by the act of God, or that of the obligee himself, or becomes by any means illegal, the penalty of the obligation is, in any of these ca saved, and the obligor discharged from all liability; for no prudence or foresight on his part could guard against such a contingency. But although the whole penalty, by breach of the condition, may become payable, the courts will confine the liability to the actual amount due, or the actual damage sustained by the breach.

BOND, POST OBIT, is a bond in which the main con dition is, that it only becomes payable after the death of some person whose name is therein specified.

BONDAGE, bond'-aj, properly denotes a state of servitude or slavery, and by English law-writers it is used in the same sense as villenage. Bondage by the forelock was when a freeman renounced his liberty and became the slave of some great man, which was done by cutting off a lock of hair on the forehead and delivering it to his lord. Such an one, if he reclaimed his liberty or escaped from his master, might be drawn again to his servitude by the uose; whence the phrase, To pull a man by the nose. The Romans had two kinds of bondmen,—the servi, who were either bought, taken in war, or acquired in some other lawful way; and verne, those born of their bondwomen. Justinian mentions a third class, called adscriptititi gleber, or agricantit, who were a species of serfs or boors, not bound to the person, but to the ground or place, and belonged to him who possessed the land. These, by our law, are termed villain regardants.

Bone, bone, in Anat., is a hard complex structure. forming the framework or skeleton of the body in man and the higher animals. It is confined to vertebrate animals; and even in the lowest order of this class. bones form a framework for the moulding and adethe cartilaginous fishes, it is entirely wanting. quate support of the soft parts of the body; cavities for the lodgment and protection of delicate organs: joints for locomotion, and levers for the action of the muscles. They are always in the interior of the body and even when they approach the surface are covere by some soft membrane, muscle, skin, &c. The first development of bone is commonly—though not always, as in the bones of the head—preceded by the formation of a cartilaginous structure, occupying the place which the bone is afterwards to take. It has commonly been said that the bone is formed by the ossitication of the cartilage; but this, for various reasons, is thought not to be the case. The process of bone-formation always commences in the immediate neighbourhood of blood-vessels, which pass down into canals excavated in the substance of the cartilage, and lined by a continuation of its investing membrane. Hence the spots where these vascular canals are especially developed are termed centres of ossilication. One of these is are termed centres of ossification. One of these is usually found in the centre of the shaft of a bone, and one at each end, with an additional one for any considerable projection or process. In the flat bones there is generally one in the middle of the surface, and one in each of the principal processes. Until the bone

astains its full dimensions, the parts which contain distinct centres are not connected by osseous union, but only by cartilage, so as to allow an increase in the size of the hone by the growth of cartilage between its detached portions, which gives place to bony structure when there is no further need of increase. There exists a close correspondence between the number of ossific centres in the early condition of the skeleton of all vertebrated animals. The growth of bone is effected by the addition of new tissue in three different modes : 1. By the development of new bone in the cartilage between the parts yet remaining separated; 2. by the development of new bone in the membrane covering development of new hone in the membrane covering the surface; and 3. by the interatitial formation of new layers within the canals of the osseous fabric already developed. The perfect reparation of bone after severe injuries, effected by the development of new osseous tissue in the substance of membrane or cartilage formed in the seat of injury, is one of the most remarkable features of its character. Bones are so constituted that a constant process of deposition and absorption is carried on in them, as in the softer diseass, modelling the shaft into its requisite proportions during the successive stages of growth. much more actively carried on in youth than in middle life, and is greater in the vigour of manhood than in old age. Bones increase in length not so much by interstitial deposit, as by addition to their ends; that is, by progressive ossification of the layers of cartilage which intervene between the ends of the shaft and the epiphyses. Bones are largely suppned with photo-recovery. The solid osseous texture which forms the cylindrical the thick external plates shafts of the long bones and the thick external plates of the denser flat bones is penetrated by a series of inrge canals, termed Haversian (after their discoverer). which form a network in its interior, and serve for the transmission of blood-vessels into the interior. These causis, in the long bones, run for the most part in a direction parallel to the central cavity, and communicate with this, with the external surface, and with each other, by frequent transverse branches. They vary in diameter from the to whom of an inch, averaging about the bone is most compact; but become gradually larger towards the interior. In the long bones of man and of most mammalia there is a central cavity, which is filled with the fatty substance known as marrow; and the space in which the marrow lies is called the medullary canal. This cavity does not exist in the bone in its early state, but is formed by the removal of the cancellated osseous tissue first developed in its interior. Among birds, however, the central cavity, instead of being occupied by marrow, is filled with air, and communicates with the lungs; so that the membrane lining it becomes an auxiliary organ of respiration; whilst the lightening of the bones thus produced diminishes their specific gravity. Bones are covered externally by a strong fibrous membrane termed the periosteum, which serves to protect the blood-vessels entering them. The medullary canal is also lined by an extremely delicate membrane, termed the medullary membrane, which supports the marrow, and provides a stratum for the subdivisions of the medullary artery before they penetrate the contiguous osseous substance. The Haversian canals are also lined by a similar membrane. Though bones possess little sensibility in health, yet, when diseased, they become highly sensitive, a manifest indication that they are supplied with nerves. These may, indeed, he traced into some of the minute foramina on the shaft of a long bone, but more easily into the articular ends. nerve also enters the medullary caral with the nutrient artery of the medulla, and divides, like the artery, into an according and a descending branch. Bone is composed of a basis of animal matter, imprepated with "bone-earth," or phosphate of lime. The first ingredient makes it tenacious and elastic; the second gives it the requisite hardness. These may be separated from each other: the latter may be entirely dissolved away, by soaking the bone in dilute muriatic or nitric acid, when a substance of cartiliginous appearance is alto a market of the former, by subjectify the bone to a heat tordicent to decompose the animal matter, when we obtain the whole calcareous substance in situ. The bone manure has been known to raise the value from the satural portion of a bone forms about one third, the loss to 40s. per acre. In 1859 Great Britain imported

earthy about two thirds; and the relative propos of the two elements is said to differ little in diffe of the two elements is said to differ little in different classes of animals. It is not yet a settled point whether the proportions vary at different periods of life; has the general opinion is that they do, the animal alement predominating in early life, the earthy in old age. The bony framework of the higher classes of vertebrate animals presents very nearly the same chemical cha-racteristics in most individuals. Bones, when dried at 212° until they cease to loss weight, consist of one third ossein, or organic matter, and two thirds of phosphate ossein, or organic matter, and two thirds of phosphate of magnesia. Ossein, when boiled in water, gradually dissolves, leaving a small quantity of fatty and vascular matter floating on the solution, which, on cooling, gelatinizes, forming a weak glue or size, consisting of nearly pure gelatine. The earthy matter may be separated from the ossein, either by means of an acid, or else by boiling in water in a Papin's digester, at a temperature over 300°, the gelatine being only dissolved at that heat, (See Boiling-Points.) The mineral constituents of bone are used as manure and in the manufacture of cupels. (See Bonk-Ash.) When bones are distilled in close vessels, at a gradually increasing temperature, oily matters, mixed with carbonate of ammonia, pass over, leaving behind bone-black, or animal charcoal. (See Bonk-Black, Bonk-Luquok.) The following are the analyses of ox-bone by Berzelius, and of the human fore-arm by Hemtz :-

	Ux-Done.	Human tole-run

Potash and soda salts	. 2.45	<u> </u>
	100:00	100:00

The great value of ground bones as manure depends upon the quantity of phosphate of lime contained in them: hence battle-fields are notably fertile. Ground bones are now generally prepared for manure by adding a certain portion of sulphuric acid to them, by which means a superphosphate of lime is formed, which is soluble and easily absorbed by the plants to which it is applied. (See ANATOMY.)—Ref. Carpenter's Principles of Physiology; Holden's Human Osteology; Quain's Anutomy.

BONE (in Manf.). - Bones, in a great variety of ways, They are give employment to manufacturing skill, used by turners and cutlers, but their oil must be previously extracted by boiling, and they are afterwards bleached in the sun or with chloride of lime. This, unfortunately, renders them more brittle and less easy to turn. The form and nature of most bones, with their large cavities for marrow, are also unfavourable to their being worked into common articles of domestic use, such as knife-hundles, brushes, &c. The buttock use, such as knite-handles, brushes, &c. The buttock and shin-bones of the ox and calf are the bones most generally used. Common bone articles, such as nail and tooth-brushes, are often polished with sized nime used wet on flauncl or woollen cloth. Bones are also used for making animal charcoal; and, when calcined, bone-ash. (See Bone-Ash.) The scrating with the statement of th pings, parings, and sawdust of bones, are much used in making gelatine for the confectioner, and also in case-hardening small objects in steel. In Manchester, bones are boiled in open pans for twenty-four hours, when the fat is skimmed from the surface and sold to soap and candle manufacturers. The size which is left is boiled down until it is of sufficient consistency for stiffening the goods for which it is intended. The pasture and grass lands, and the residual bones are readily bought up by the farmers. A very good liquid manure is also made by digesting burnt bones in weak sulphuric soid. This affords a direct solution, con-taining superphosphate and sulphate of lime, which is useful for grass lands or fields of rising corn. If pearluseful for grass lands or fields of rising corn. If pearlash is added to this acid solution, and the mixture dried

## Bone-Ash

rly 85,000 tons of bones, valued at £500,000. In the surry co,000 tome of rones, valued at 2500,000. In the surren steppes of Tartary and in the Pampas of South sacrica bones are used as fael; and in Norway and weden, in times of scarcity, fish-bones are browned a a gridiron till they are friable, and with ealt and super form palatable food. (See Ivorx.)—Ref. Ivons. The Society of Arts—"On Bone and its Uses," by leaver at the of mry Aitken.

Senty Aithen.

Bons-Ass, the mineral constituents of calcined bones, containing the whole of the earthy matter.

Bone-ash cousists principally of phosphate and carbonate of lime, with a small quantity of phosphate of magnesis and chloride of sodium. By dissolving bone-ash in hydrochloric acid, and precipitating by means of manorins, its most valuable component, phosphate of sime, is produced nearly pure. Bone-ash is largely used in the preparation of artificial manures, and in making cupels for assaying purposes.

BONE-BLACK.—When bones are subjected to destructive distillation, a black granular earthy mass is

structive distillation, a black granular earthy mass is left behind in the retort. This contains phosphate of lime, carbonate of lime, and charcoal, and is extremely rainable, from the property it possesses of decolourizing vegetable substances. It is therefore much used as a descolourizing agent in various processes, but more particularly in sugar-refining, for decolourizing the brown straining in augar-reining, for decomment of the symp. When used for chemical or pharmaceutical surposes, it is digested with hydrochloric acid until actining remains but nearly pure carbon. This promerts is due to its very firm state of division. The porty is due to its very firm state of division. The coarser varieties of bone-black are used in the manu-

facture of blacking. (See Charcoal.)

BORE-LIQUOR.—The liquor which distils over during the preparation of hone-black divides into two parts,one a mixture of various oils, and the other a solution of carbonate of ammonia, or bone-liquor, as it is called. It is much employed in the manufacture of the solution

and salts of ammonia.

BONFIER, bon'-fire (Fr. bon, good; Sax. fur, fire), a fire made for some public rejoicing, usually in some conspicuous place; as on the top of a hill, we some conspicuous part of a town, so as to be visible from a distance. The etymology of the term is very doubtful; some suppose it to have been so called from being generally made of bones; others consider it to mean a contribution fire, one to which every one in the neighbourhood contributed a certain portion of materials; others derive it from boon or bon, good, and fire. The practice of kindling bonfires in this country is one of great antiquity. (See BELTEIN.)

BOXNOMMES, bon'-om, an order of hermits of simple lives and manners, who made their appearance in France about 1257. The prior of the order was called France about 1257. The prior of the order was called by Louis VI. le bon homme, whence they derived their me. They made their appearance in England in 1283.

BONTTO, bon'-e-to (Sp.), a name applied to several thes belonging to the fam. Scomberidæ. There are three varieties,—the Thynnus pelamys, the Pelamys surda, or Belted Bonito, and the Auxis vulgaris, or Plain Bonito. Plain Bonito. The T. pelanys resembles the tunny, and is not unlike a large mackerel. In tropical climates it is found in large numbers, and is well known to sailors as one of the fishes constantly seen in pursuit of the flying-fish. It is a very pretty fish, of a rich fluse colour, with four dark lines stretching from the pectorals to the tail, on either side of the belly. Its average length is about two feet, and it is generally manche with an implation flying-fish as a bait. The The T. pelamys resembles the tunny, saught with an imitation flying-fish as a bait. The Black Sea. The plain bonito is also found in the Mediterranean, where its flesh is salted or pickled, and sed for food : but it is never eaten when fresh.

SORRER, bon'net (Fr. bonnet, cap), in Mil., the ele-stion of the parapet about the salient angle of a salion or ravelin above the general level of the work. The name is also given in permanent defensive works to a little outwork with two faces, forming a sulient gie, intended to protect the angle of a ravelin (see Rayking), the faces of which are defended by tenailess or lunettes. (See TENAILLON, LUNETE.) An ontwork of a similar kind, used in Beld fortification, having three salient angles instead of one, is called a

mest de prêtre, or priest's bonnet.

Bongsar, a covering for the head, of which there
is many varieties. It is applied to the head-dress

#### Book

In Scotland the "blue bonnet" of either sex. one time the national characteristic of the low land Scotch, and was famous both in song and story. It was manufactured of thick milled worklen, and was broad, round, and flat in appearance, with a small red tuft on the top. It is still worn to a considerable ex-

tent on the top. It is still worn to a considerable ex-tent by the peasantry of that country.

BONY PIKE, pike (Lepidasteus ossess), an elongated pike-like fish, inhabiting the warmer lakes of America.

The jaws of this fish are usually produced into a long narrow snout, presenting considerable resemblance to that of the Gangetic crocodile. The vertebral column presents a structure such as is met with in no other fishes, the bodies of the vertebræ being regularly arti-

culated together.

BONES, bonz-es (Japanese Busso), the name by which the priests of Buddha or Fo are usually designated in Japan. They form a very numerous class in that and are composed of all ranks of society. country, and are composed of all ranks of society. They are divided into various sects, and comprise both males and females. There are convents for the male as well as for the female bonzes, some maintained by voluntary contributions, others having their own fixed revenues. The principal moral precepts which they inculcate are five; namely, not to kill, not to steal, chastity, veracity, and abstinence from spirituous liquors. The term bonzes is also frequently applied by Europeans to the priests of Buddha in China, the Burance contributions of the state of the contributions of the state mese empire, and other parts of eastern Asia.

BOORY, boo'-be (Sula fusca), a name given to a large

bird, a species

of gannet. It is not quite so large as a solan goose, and it desolateislands and unfrequented coasts of most warm climates. has received ite name in consequence of apparent stupidity, sitting quietly and allowing itself to be knocked on the

TER BOORY.

head, or be taken away by any one attempting it. is very powerful on the wing, and feeds on fishes, which it watches while flying close to the surface of the water, and then catches by suddenly diving down upon them. Its colour is dark brown, rather white underneath. Its bill is much longer than its head, and its gullet is so expansible that it is able to swallow fishes of large size. The male and female resemble each other closely size. The mate and femate resemble each other causing in appearance, and the latter only lays one egg. The flesh of the booby, like that of all birds that live on fish, is not agreeable when cooked. (See Garner,) BOOK, book (Sax. bod) is a general name given to almost any kind of literary composition, but in a more limited sense to such as are large enough to form one or more volumes. When short conjunting only a few

or more volumes. When short, occupying only a few sheets, sewed or stitched together, it is called a pamphlet. Certain divisions of a literary work are also sometimes designated by this name; as the Books of Homer's Iliad, or of Virgil's Abucid. In ancient times books were commonly written upon prepared strips of the Egyptian plant papyrus. They were wound round small cylinders or rollers,—whence the Latin term tolamina, and our word volume. Plates of lead and copper, wood, the bark of trees, and even bricks and stone, have been employed as materials in the construction of books. Leather and parchiment were also used by the ancients, and when, by the capture of Egypt by the Arabs, in the 7th century, papyrus could no longer be obtained, the use of parchiment became general. During the Middle Ages the plan of rolls was discontinued, and the form of leaves sewedor bound together came into use. The manufacture of books was for the most part in the hands of the different orders of monks, many whom spent a great part of their lives in the transcrib-ing of them. In the earlier part of the Middle Ages the

#### Bookbinding

Book-keeping

scarcity of books was so great that often in a whole town there was not one to be found, and even rich monesteries possessed little more than a missal. The leadure of the monks, however, did much to improve this state of things; white the general introduction of paper about the 13th century, followed by the invention of printing, have been of incalculable benefit in the circulation of knowledge. Books may now be had for a few shillings, which would formerly have cost hundreds of pounds. (See Book Talle.)

HONERSTING (Ang. Sax.).—Books were formerly preserved in the form of rolls, consisting simply of the caree pasted or guide together in one long sheet, at each

leaves pasted or glued together in one long sheet, at each end of which was fixed a roller with handles. The roll was read by unwinding one roller and winding the other. This form of binding was afterwards superseded by the square form, as we now possess it. This was a marked improvement, and was adopted for manuscripts long before the invention of printing. The first bound books being chiefly copies of the Scriptures, and other works of a religious nature, they soon began to have their bindings enriched in various ways. Many of these ondings enriched in various ways. Many of these rich bindings exist to the present day. They were executed principally by jewellers, who incrusted pre-cious stones, ivory, and metal-work upon covers of volums, wood, or silver. The greatest taste has been shown in all ages in the matter of bookbinding; and shown in all ages in the matter of bookbinding; and
whether we examine the gorgeous but clumsy covers
of the 11th and 12th centuries, the splendidly-bound
books of the Renaissauce period, or the modern works
of Rogers, Leighton, Bedford, and a host of others,
there is always something to charm the fancy and gratify the taste. As a mere manufacture, bookbinding has been obliged to keep pace with the marvellous increase in the number of books produced; and, by means of machinery, such houses as Remnant's or Leighton's are able to bind 1,000 volumes, in cloth gilt, Legaton's are able to find 1,000 volumes, in citof git, in six hours! In binding a book, whether it be a tenguinea folio by Owen Jones, or a 2s. 6d. volume of the Boy's Magazine, the number of operations is three; viz. 1. Preparing, 2. Binding, 3. Finishing. The sheets as printed are first "gathered," that is, placed in their order of pagination, folded into four, eight, or twelve leaves, as the case may be; they are then stitched and sewn to strings or bands placed at the back of the volume. A saw-out is, in some instances, made to receive the string; in others the string is left to form a rib, which is used as an element of ornament in finishing the book. The sheets being all sewn together, the back edges are glued together by brushing them lightly with thin glue. The strings are cut off within hilf an inh of the volume and the hard is recorded. half an inch of the volume, and the back is rounded in the following manner:—The workman holds the volume flat, and beats it with a flat hammer, at the same time drawing the sheets so as to cause the rounding of the odges. A groove is then formed by pressure close against the back edge to receive the board of the cover, otherwise it would be liable to project beyond the edge of the volume, and be both unsightly and inconvenient. A machine for rounding the backs of books has been lately introduced. The top, bottom, and front edges are then cut level, and the boards are fixed to the volume by the ends of the strings being passed through small holes and glued firmly to the inside. When the book is cloth-bound, the cloth is applied to the boards before they are attached to the volume; in other cases the coverings are put on after the boards are attached. The rerings are put on after the boards are attached. The book is then ornamented with gilding, inlaying of differ-ent-coloured leather, or blind tooling, i. e. plain stamp-ing by heated stamps or dies, and the edges are left plain, or git, or sprinkled. Books are said to be "boarded" when bound in cloth, "half-bound" when the back and corners are in leather, and "whole-bound" when nothing but leather is used. It is generally considered that hearded books will be afterwards bound in leather nothing but leather is used. It is generally considered that boarded books will be afterwards bound in leather, according to the teste of the possessor; they are, therefore, mostly left uncut, and the putting together is more or less slight. A method of binding without without here has lately been much used the form addeen. is more or less slight. A method of binding without stitching has lately been much used: the four edges of the book are out, separating it into single leaves; India-rubber solution is then applied to the back edge, whereby the leaves become firmly cemented together. It is very useful when the book is required to be laid epsil flat, as in the case of atlases, ledgers, music-books, &c. The following is a list of the most common sizes

of books, with familiar examples to fix them as t of books, with familiar examples to fix them an memory:—Folio, the volume of 100 plates to Layse "Monuments of Nineveh;" quarto, the "Encyclopes Britannica," and "Beston's Family Bible;" out "Beston's Universal Dictionary" and the "Moown Magazine; "10mo, Peter Parley: A Tales: 18 Pinnock's Catechisms, and Knight's Weekiy Volume 24mo, Routledge's "American Poets;" 40mo, Picking, "Liberand Cleanies" no, Picker ing's " Dismond Classics.

BOOK-REEPING (Ang. Sax.) is the art of keeping accounts,—the art of recording in a regular, concise and accurate manner, the business transactions of merchants or others, in a set of books kept for the purpose. Of the early history of book-keeping little is known. In the 15th century the double-entry system was practised by the merchants of Venice and other towns of Ituly, then the great mercantile country of the world, whence it has obtained the name of the Italian method. In the early part of the 16th century it had been introduced into France; and the first the tise in England upon the subject was by Eugh Old-castle, a schoolmaster, and was published in 1543. Since that time more than 150 different works have been published in this country upon book-keeping. Books are kept either by single or by double entry. The system of single entry is the simplest method of keeping accounts; but it is only suitable for retail dealers, or such as carry on but a small business, being wholly inadequate to the recording of complex traactions. It receives its name from each item being entered only once in the ledger. The only books neces-sary for it are a journal, or day-book, and a ledger. In the former the merchant enters all his transactions as they occur in the course of business; in the latter be arranges them under their several accounts, carrying his sales to the debit of his customers, and his p chases to the credit of the merchants who supply t with goods. The system of double entry is so called from each item being entered twice in the ledger, being debited to one set of accounts and credited to anoth It proceeds upon the principle, that every business transaction is twofold,—that there can be no sale without a purchase, no payment without a receipt; and hence, by entering each transaction on both sides of the ledger, a system of checks is established, iene much as the entries on the credit side must be equal to the entries on the debit side, otherwise the books will not balance. Although book-keeping is a system beautiful and complete in itself, yet its details necesssarrly vary according to the nature and extent of the actions to be recorded. It is alike applicable to the accounts of merchants, manufacturers, or public com-panies; but the mode of carrying out the details will vary in each case. Its object is to secure a clear and condensed statement of every fact and transaction connected with the business, so that it may be at once understood, and that accuracy may be secured. less a merchant knows how his affairs stand, less a merchant knows how his affairs stand,—the amount of his income and expenditure, of his debts, and his liabilities,—it is evident that he must proceed upon vague and possibly erroneous conclusions, which may result in insolvency. The number of books required in double entry will depend upon the nature and extent of the business. In the case of merchants the books commonly used are the day-book, invoke-book, cash-book, bill-book, and ledger. In the day-book, cash-book, bill-book, and ledger. In the day-book and proceed a daily account of all the goods soid on credit, with the uniter with the nature of the numbers. with the prices and the names of the purchasers. invoice-book, called sometimes the credit day-book, conthins an account of all goods bought on credit, with the name of the seller and the amount. In the cash-book is kept an account of all the cash received and paid, and of the discount received and allowed. On the left-hand page is entered the cash received, and is an inner column the discounts allowed; and on the right-hand page the cash paid, and in an inner column the discounts received. At the close of business for the discounts received. At the close of business for the day, the amounts on both sides are summed up and bulanced. The bill-book gontains in one part as account of all the "bills receivable,"—i.e., bills of which he is to receive payment; and in another as account of all "bills payalle,"—i.e., those that have to be paid. It contains a statement of the dates, amounts, when due, and other particulars of the

several bills. All these books are very simple in their character, and are usually termed "sub-sidiary books," the *ledger* being the principal book in a business. It contains an abstract of the entries scattered through the various subsidiary books, all arranged methodically under the names of the different persons standing in the relation of debtors or creditors to the merchant. Two sets of columns are assigned to each account, one for Dr., the other for Cr. Besides these accounts, which are termed personal from being made out in the names of the persons with whom the merchant has dealings, there are what are termed real and fictitious accounts. Real accounts are made out to show the merchant where, how, and in what proportions his property is invested, under such heads at cash, merchandise, bills receivable, and the like. Rectitious accounts are such as are made out to show his gains and losses, under the heads, charges, profit and loss, balance, &c. The fundamental principle of double entry, that every item carried into the ledger must be entered twice, must be entered on the Dr. side of one account, and the Cr. of another, leads to the result that the aggregate amount of all the entries on the Dr. side must exactly balance those on the Cr. side of the ledger. The account giving out the item is always the ledger. Or., and the account receiving it always the Dr. copying of the items from the subsidiary books into the ledger is termed "posting." To facilitate the post-ing of the ledger, an intermediate book called the journal is sometimes used. Its object is to indicate to what accounts, and to which side of each account, the transactions recorded in the subsidiary books are to be carried. It is also found most useful in practice as a check against posting entries to the wrong accounts in the ledger. The balance-sheet is a condensed statement of the merchant's assets and liabilities, drawn up in order to show the state of his affairs. His assets are found in the balances on the Cr. side of the ledger accounts, and these are put on the Dr. side of the balances heet. His liabilities are the balances appearing on the Dr. side of his ledger accounts, and these are brought to the Cr. side of the balance-sheet. The difference between his assets and his liabilities is his present worth. A proper balance-sheet ought to show the manner in which the capital was invested, as money, stock, debts, &c.; also the expenses at which the business had been conducted, and the money drawn out on private account. "Let no man," says Dr. Johnson, venture into large business while he is ignorant of the method of regulating books; never let him imagine that any degree of natural abilities will enable him to supply this deficiency, or to preserve a multiplicity of affairs from inextricable confusion."

BOOK OF LIFE, OF THE LAMB'S BOOK OF LIFE, is one of those descriptive phrases of which there are so many in Scripture, by means of which a knowledge of divine things is communicated by referring them to objects or customs of daily life. It was the custom with princes to have a list of all the distinguished persons about their court, or in their service; and hence, when it is said that one's name is written in the book of life, it means that he particularly belongs to God, and is enrolled among his friends and servants. On the other hand, to have one's name blotted out of the book of life signifies erused from the list of God's friends and ser-

riginies erased from the list of God's friends and ser-rants, as those who were guilty of treachery were struck off the roll of officers belonging to a prince. BOOKELLERS' MARKS OF SIGNS.—Many of the early printers, or booksellers, in place of putting their name on the title-page of their books, adopted a certain mark or sign; and hence a knowledge of these marks is of use in distinguishing different editious of works. The anchor is the mark of kaphelengius at Leydon; the anchor with a dolphin twisted round it that of the anchor with a dolphin twisted round it, that of Manutii at Venice and Rome; the Arion, of Operinus at Basel; the cadnesus or Pegasus; of the Wecheliuses at Paris and Frankfort; the cranes, of Cramoisy; the compass, of Blantin at Antwerp; the fountain, of Vas-cosan at Paris; the sphere in a balance, or Janson and Biser at Amsterdam; the filly of the Juntus at Venice, Plorence, Lyons, and Rome; the mulberry-tree, of Merel at Paris; the olive-tree, of the Stophenses at Paris and Genoa, and the Elzevirs at Amsterdam and Leyden; the bird between two serpents, of the Fro-benius at Basil; the Truth, of the Cornelius at

Heidelberg and Paris; the Saturn, of Colinmus; the

printing-press, of Badius Ascensius.

Book Societies, or Book Churs, are associations for the purchase and circulation among themselves of new books as they issue from the press; after which they are usually disposed of by auction among the members, or sold to the public. Book societies are by no means so common as, from the many advantages of them, they might be expected to be. Book clubs, or reading societies," says Lord Brougham, in his "Pra-tical Observations on the Education of the People may be established by very small numbers of contributors, and require an inconsiderable fund. If the associates live near one another, arrangements may to associates live near one another, arrangements may be easily made for circulating the books so that they may be in use every moment that any one can spare from his work. Here, too, the rich have an opportunity presented to them of promoting instruction without constant interference; the gift of a few books as a because of the state of the st ginning will generally prove a sufficient encouragement to carry on the plan by weekly or mouthly contributions

BOOK-TRADE,-The business of dealing in books is of a comparatively recent date. In early times, when books were scarce and had all to be transcribed, those who copied them usually also disposed of them. In the later period of Roman history, however, there arose a class of persons termed bibliopole, who acted as a kind of middle-men, employing or purchasing books from the transcribers and disposing of them to the public. In the reign of Augustus, the brothers Socii were celebrated in this way. With the establish-ment of several universities in the 12th century, the trade in books was much increased, particularly in such towns as Paris and Bologna. In 1323, a statute of the University of Paris distinguishes between stationarii, or booksellers proper, those who buy from one party and sell or lend to another, and librarii, those who merely buy and sell books on commission. After 1342, no one could deal in books in Paris without the permission of the university, who had special officers to examine the manuscripts and fix the price. It was not, however, till after the invention of printing that the book-trade attained any importance. At Brst. the printers were likewise booksellers: and John Fust and Peter Schöffer disposed of the productions of their press in Paris and Frankfort-on-the-Main. Some instances of the division of the two branches occur in the 15th century. The first booksellers were usually termed stationers, either from the Latin word stationaries, or from having only stalls or stations in the streets and market-places of the towns, as is still to be seen in the case of dealers in old books. Now, the term stationer usually denotes a dealer in paper and other writing-materials. At first, the civil magistrates took little concern with the booksellers, leaving them to the control of the universities, of which they were supposed to be the immediate retainers, and which, accordingly, gave them laws and regulations, examining the correctness of their books and fixing the prices of them. This, however, was soon changed, and the trade of books calling was put under various restrictions. In 1550, the Stationers' Company of London was incorporated. It was composed of printers and booksellers, who ex-ercised a kind of censorship over the press. In 1862 the famous licensing act was passed, which prohibited the publication of any book unless extered in the rethe publication of any book unless critered in the re-gister of the Company of Stationers or licensed by the lord chancellor. (See STATIONERS' COMPANY and COPYRIGHT.) The book-trade is, properly epeaking, carried on by two distinct classes of persons,—the publishers, who prepare and dispose of the books wholesale; and the booksellers, by whom they are retailed to the public. According to the census of 1851, the number of persons engaged as booksellers and pub-lishers in England and Wales was 6,805, and in Scotlisters in England and water was 0,800, and in Scot-laud 1,489. The great centre of the book-trade in the United Kingdom is London, though a considerable number of works are also published in Edichurgh, Dublin, Oxford, Cambridge, Glasgow, and other provin-cial towns. Many provincial publishers, however, have branch establishments in London, and all of them have agents there, to whom they consign a certain number of copies of every work they publish, and to whom they also address their orders for copies of such books

## Book-Trade

as they may have occasion for. The hooksellers of Edinburgh and Dublin also act as agents for those of London, and supply the Scotch and Irish trade with the metropolitan publications. The London publishing trade centres chiefly in Paternoster Row (popularly known as "the Row") and the courts adjoining. "In 1860 there were connected with the book-trade, within the bounds of the metropolitan Post-office district, 211 booksellers who were also publishers, 568 book-211 hooksellers who were also publishers, 568 booksellers alone, besides 23 foreign booksellers and 12 law
booksellers; total, 812."—(Chambers.) Many of the
publishers and booksellers restrict their attention chiefly to certain classes of books; as theological, law, medical, general literature, &c. The average number of volumes of new works, exclusive of pamphlets, published annually in the United Kingdom exceeds 4,000; and of new editions, upwards of 1,200. In 1852, the booksellers of London formed a kind of trade-union, books only at the regular fixed price; but the attempted to compel retailers to sell books only at the regular fixed price; but the attempt entirely failed, and retailers may now sell books at any price they please. The deduction allowed by the pubprice they please. The deduction allowed by the publisher to the retailer is usually 25 per cent., or 3d. per shilling. It is also placed on a half-yearly or yearly account, from which, if settled by cash within a month after being rendered, a discount of 23 per cent. is al-lowed. Frequently, a work is, "subscribed" for among the trade; i. e. booksellers put down their names for a certain number of copies of a work before it is pub-lished, it being then offered at a somewhat lawer rete lished, it being then offered at a somewhat lower rate than is afterwards allowed. In order to get rid of re-mainders of books, trade-sales are often had recourse to, when they are either offered in small quantities at a very reduced price, or sold in the lump by auction.
Publishers wishing to dispose of a portion of their
stock sometimes issue to the trade sule-catalogues, in
which they offer certain books at a greatly reduced price. Trade dinners are not so frequent now as formerly though it is still the practice with some of the larger publishers to invite their acquaintances in the trade to a dinner at a tavern, when those present have an opa dinner at a tavern, when these presents are of copies portunity of subscribing for a certain number of copies. The of the books offered for sale at the stated price. terms of the agreement entered into between a publisher and an author are various, depending chiefly upon the character of the author and the nature of the book. Sometimes the publisher purchases the copyright for a fixed sum, and takes the whole responsibility of the sale upon bimself; sometimes the author retains the copyright, undertakes all risks, pays all expenses, and allows the publisher a certain commission on the sales; sometimes the publisher agrees to take all the risk of printing and publishing a certain number of copies, and to divide the profits with the author, who still retains the copyright of the work. Authors are apt to complain of the hard terms that are usually meted out to them by publishers, and in some cases, perhaps, not without reason. But it is to be borne in mind that there is always considerable outlay, and no little risk, connected with bringing out a new book, especially by an unknown author. The following is the especially by an unknown author. The following is the estimated cost of bringing out 750 copies of a work of 500 pages

Printing and corrections	£85
Paper	30
Boarding in cloth	24 30
Advertising	30

Were all the copies sold (after deducting those for presentation) at 7s. 6d. each (i. c. the trade price of 10s.), 25 counting as 2s, there would remain about £90 for interest on capital and publisher's and author's profit. But this is rarely the case, and frequently the sale does not meet the actual outlay for printing and apper. Not more than one book in eight ever reaches a second edition. There have been instances (we fear rare) of publishers handsomely increasing the stipulated remuneration, when the sale of a work largely exceeded their expectations. The Messrs. Blackwood, of Edinburgh, at first gave the Rev. J. Caird £100 for bis sermon "Religion in Common Life," but the sale of accessed their expectations, that they subsequently presented the author with £400 in addition; and the projector of the present work brought out an edition of

#### Book-Trade

"Uncle Tom's Cabin," which was so successful, that he voluntarily presented the authoress with £500, and subrequestly presented the authors when the book is has been calculated that 1,500,000 copies were sold in Eugland, 'Mr. Beeton's firm alone issuing 697,000.) The epoch of cheap literature may be said to have commenced, however, partially in 1827, when Constable issued his "Miscellany," and the Society for the Diffusion of Useful Knowledge their "Library of Useful Knowledge their "Library of Useful Knowledge "On the 4th of February, 1832, appeared Knowledge." On the 4th of February, 1832, appeared the first number of "Chambers's Edinburgh Journal," and, on the 31st of March following, "The Penny Magazine." Soon after was commenced "The Penny Cyclopædia" of the Society for the Diffusion of Useful Knowledge, a work not more remarkable for its cheapness than for the ability with which it was conducted. Forty thousand pounds was distributed amongst the authors and artists engaged in its production, of which sum more than three-fourths had been laboriously carned by the diligence of the writers. Cheap publications are now the order of the day. Not only are chesp editions brought out of works unprotected by copyright, but even publishers of the first class find it their interest to bring out cheap editions of popular books the copyright of which is secured to them. Among the names chiefly entitled to honourable mention in the field of cheap literature, we may, without detracting from the merits of others, give those of Charles Knight facile princeps, the Chambers' of Edinburgh, Bohn, and Routledge. It is now usual to stereotype cheap books and periodicals of which the sale is expected to be considerable, or to extend over a considerable time; and this course is adopted even with large books like the "Encylopædia Britannica." The old-book trade, or the sale of second-hand booke, is carried on to considerable extent in all the larger cities and towns of the United Kingdom; but London is its principal of the United Kingdom; but London is its principal seat. Many of these dealers prepare periodically price catalogues of their books, which they circulate through the country, and in this way dispose of a great many of their books. The price of old books is very fluctuating and capricious, depending in some measure upon this could be considered. their condition or intrinsic value; but frequently equally good copies of the same work may be had at a half or third of the price in some shops that they can be obthe book-trade is Leipsic, where two great book-fairs are held annually, at Easter and Michaelmas respectively. These fairs are not so important or so largely attended now as formerly, a great part of the business being effected by means of agents or commissioners. Every bookseller in Germany has his commissioner at Leipsic, to whom he transmits copies of all his new publications, and who distributes them among the other commissioners, for being transmitted to their employers. At the end of the year the unsold works are sent back by the same means to their several publishers. The great advantage of this system is that every new book is, within a few weeks of publication, made known throughout Germany without having recourse to the expensive and imperfect system of advertising. The accounts of the various booksellers are also usually settled by means of the commissioners. In France the booktrade is carried on much in the same way as in England, and centres in Paris. In the United States of America. the book-trade is carried on to a large extent, and on account of non-existence of international copyright, the books of this country are largely reprinted there. It is indeed asserted that while, in 1820, of the number of books published in the United States, 70 per cent. were reprints of British publications, in 1856 the proportion was only 20 per cent. But it is undeniable that the best books of this country are still reprinted with-out authority in the United States. From the low price out authority in the United States. From the low price at which reprints of popular English books can be produced, the sale is often four or five times greater than queed, the sale is often four or five times greater than in England. It is said that in five years there have been sold in the United States 80,000 vols. of the 8vo edition of "Modern British Essayists," 60,000 vols. of Macsularies, in 3 vols. 12mo; more than 50,000 of Murray's "Eucyclopædia of Geography," 10,000 of McCulloch's "Commercial Diotionary," more than 100,000 of "Jane Eyro." The sale of Thackersy's works in the States has been engaging that it England: and in the States has been quadruple that in England; and that of Dickens's works counts by millions of volumes.

317

## Boom of a Harbour

"In 1853," according to Trübner's "Bibliographica Guide to American Literature" (1859), "there were 355 book-publishing establishments in the United States." At present the number is more than 400. About three-fourths of these are located in New York, Philadelphia, Baltimore, and Boston, the rest being principally in Cincinnati, Charleston, New Orleans, Buffalo, Auburn, Albary, Louisville, Chichago, St. Louis, and Hartford, There are more the 2000 hockession, who discount who discount There are more than 3,000 booksellers, who dispense the publications of these 400 publishers, besides 6,000 or 7,000 general dealers, who connect the trade in books with the ordinary stock of a country store." The book-trade of 1856 is estimated at 16,000,000 dollars. An interesting article on this subject, by Mr. W. Chambers will be found in "Chambers's Eucyclopædia." also "Bookselling," in Encyclopedia Britannica;
Books," in McCulloch's Commercial Dictionary;
Trübner's Guide to American Literatura; and Trubner's Guide to American Literatura; and the Modern Press, by Charles

Knight. BOOM OF A HARBOUR, boom (Du.), a term applied to a strong iron chain or cable fastened to a number of spars or poles, and drawn across the mouth of a harbour, for the purpose of preventing the entry of an enemy's ships of war. This chain or cable may be raised or lowered above or below the surface at pleasure, by means of capstans and other mechanical consults.

trivances. BOOMERANG, beom-s-rang', a missile instrument used by the aborigines of Australia, in war, sport, and the chase. It consists of a piece of hard wood of a bent form, with the curve of a parabola, is about 2 feet long, 24 inches broad, & inch thick, and is rounded at the extremities. One side is flat, the other convex, and it is brought to a bluntish edge. It is discharged by the hand by one end, the convex edge being forward and the flat side upward; and it is thrown as if to hit an object in advance; instead, however, of going forward, weapon among almost the lowest races of savages upon the earth, and was first made known in this country by Professor McCullagh, in 1937: since then it has been endeavoured to apply the principle of the boomering to the propulsion of ships.

Boon, boor (Du. boer; Gor. bauer), properly signi-

fles a countryman, or one who is employed in agri-cultural labour; and from that it has come to be used in a secondary sense, to denote a coarse, uneducated. clownish person.

"The boorish driver leaning o'er his team Vocil'rous and impatient of delay.

Boor, or Bordenin, boof, a mode of torture used in former times in this country, our more persons Scotland, in order to extort confession from persons accused of crimes. This instrument of torture, which acoused of crimes. This instrument of torture, which was applied to the leg, was of various kinds. Sometimes it was composed of parchiment applied moist, and then brought near the fire, so as by shrinking of the compositions o to cause great pain and uncasiness; sometimes it round either one or both legs with cords, and then tightened by means of wedger, until, occasionally, the bones of the unfortunate sufferer's legs were broken; This barbarous piece of torture-apparatus is also said to have been made of iron.

BOOT AND SHOR MANUFACTURE. - This useful manufacture, as now followed in London and other large towns, is divided into many branches. There is the shos-closer, who is generally a woman,—she prepares attaches the sole part to the upper-leather; the book conser, who prepares the leg and vamp portion of the boot; the bootman, who attaches the sole part to the sather, similarly to the shoeman; the jobber who is allocated the sole and the blocker, chicker, runer, cleaver-up, &c. Many

## Bootes

persons of both sexes are employed in the manufacture of boots and shoes in this country. Till 1846 it was an ordinary handicraft; but, since that time, the manu-facturers of Northampton and Stafford hase introduced sewing-machines, by means of which much of the former labour is dispensed with. These two towns have for many years been the principal sources from which the London market has been supplied; and their boots and shoes are considered to be equal to any of those made in Paris or London. Many of the so-called French boots are made by English manufac-turers with French fronts, which they import in large quantities from France; and there is also a considerble importation of French boots and shoes. In 1850 there were 165,466 pairs of boots, shoes, and goldsheimported, and 609,599 pairs of boot-fronts. The first processes in the manufacture of boots and shoes ar the cutting and sewing of the leather, which are merely mechanical. M. Lefebre, of Paris, has made an in provement in boot and shoe-making, which he has patented. By means of machinery the sole and hee are fastened to the welt by brass screws, which keer them in contact with a pressure equal to two or three hundredweight. A specimen of this machinery was shown at the Exhibition of 1851. Mansell's blocking apparatus is another of the many improvements intro-duced into this manufacture of late years. It effects the blocking of a boot in less time than the usual process, and does not injure the leather so much. A piece of leather cut into the proper shape for the front of a boot is soaked in water; the part which corresponds with the instep is then rubbed with an oily pasta called "dubling," and the whole is laid upon two iron cheeks By means of a winch and two cog-wheels, the leather is brought down between the cheeks by a plate of zinc and this process is repeated according to the strengt! of the leather. By a patent taken out by Waite, a London manufacturer, some years ago, the necessity until it resoftes a considerable height, when it begins to retrograde, and finally passes over the head of the projector and falls to the ground behind him. The projector and falls to the ground behind him. The boomerang, in one-tenth part of the time required in the bulged side of the instrument. The boomerang, the invention of which would have done henour to the most celebrated man of science, has long been a common to the bulged side of the instrument. ordinary plan. Waite has also patented a machine by which instep-pieces for women's and children's boots and shoes are modelled. By a process invented by Marsden, small holes, kept open by metallic plates, are inserted at the sides, for ventilating purposes. The use of india-rubber and gutta-percha in boot and shoe-making has produced very great changes. Gutta-percha, although not serviceable in hot climates, is very useful in withstanding moisture, when applied to the under-leather. There is also a process, patented by Hetley, in which india-rubber and gutta-percha, nixed with leather raspings, were pressed into blocks and sliced. This substance was then used as shoeleather. India-rubber is often applied to various parts of the boot or shee, in order to give lightness or elas-ticity. A pair of boots were made for a racing joolesy amost entirely of this material: they only weighed four ounces. Several terms are employed in order to distinguish the various boots made with india-rubber; such as resilient, siccopodean, and tei-ideicelasticon, &c American over-shoes, or goloshes, made of vulcanized india-rubber, are much worn, in order to protect boots or shoes in wet or cold weather. The boots worn by soldiers were formerly produced with great rapidity, by a process invented by Sir M. I. Brunel: this process, however, fell into disusc. The defective way in which they were made added greatly to the suffering of the British troops in the Crimea. They are now made with an elastic piece between the heel and the sole, which causes the shoe to accommodate itself to the bending of the foot while walking. Many unauccessful attempts have been made by workmen and trades unions to prevent the introduction of sewing-marinines into this manufacture; but they are gradusily coming more and more into use.

sily coming more and more into use.

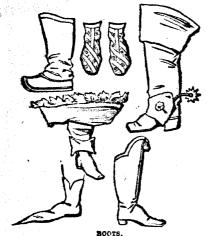

Bootus, bo-o-tee (Gr. boss, an ox), a constellation in
the northern hemisphere, called Arctophylax by the
old Greek astronomers. It is represented on the
celestial globe by the figure of a men holding a club is
his right hand and a string in his left, which holds two
hounds. Arcturus, a brilliant star of the first magnitude, is found in this constellation.

318

BOOTH, booth (Fr. boutique), denotes a tent or stall in a fair or market for the sale of goods. The term is also applied to any temporary structure of wood or boughs designed for shade and shelter. In early times throughout Europe, trade was principally carried on at fairs by means of booths:—

Booths adden hide the Thames, long streets appear And numerous games proclaim the crowded fair."

Boots, shoes, and other coverings and protections for the feet, have been made of different substances, and in different forms, from very remote times. ancient Greeks and Romans, however, did not use them universally. The heroes of Homer are represented as going to battle without shoes, and Cato and Socrates both went about with bare feet. The boots and show which were then worn may be divided into two classes,— The heroes of Homer are represented as those in which the sole only was attached to the sole of the foot by strays, or coverings of the toe or instep, and those which ascended until they covered the ankle, the call, or the whole of the leg. The former correspond call, or the whole of the leg. The former correspond to the sandals and slippers of the present day, and the latter to the boots and shoes. The form and colour of these boots and shoes indicated the rank and office of the wearer. Before the invasion of the Romans, the ancient Britons were shoes made of raw cowhide, with the hair turned outwards. They reached as far as the ankles. The Roman influence soon produced a change

in the costumes of the British. Among the early Sexons shoes were made upon the Roman model, and boots reaching to the middle of the lcg, and laced up in front, were also in common use. They were generally of leather. The sandal also began to be used; but it was not suited to this climate: it was principally worn by the clergy. The boots of the later Saxons were very simiclergy. The boots of the later Saxons were very similar to the half-boots of modern times. Boots with wooden soles were much worn by men of high rank at that period. The boots of Bernard, king of Italy, the grandson of Charlemagne, had "the soles of wood and the upper parts of red leather, laced with thongs." The Normans were boots similar to the Saxons. During the reigns of William II., Henry I., and Stephen, the toes of boots and shoes were lengthened to an extravagant extent. The illustration in the left-hand lower corner represents a boot of that period. From that time until the reign of Edward III., the boots generally worn by the higher classes were ornamented profusely. During the reign of Richard II., the length of the toes increased still more, so that it is even said that the wearers were in the habit of fastening the tips to their knees, insorder to allow them to unar period. The boots of Bernard, king of Italy, the grandson of Charlemagne, had "the soles of wood and the upper parts of red leather, lackd with thongs." The Normans were hoots similar to the Saxons. During the reigns of William II., Henry I., and Stephen, the tores of boots and shoes were lengthened to an extravagant extent. The illustration in the left-land lower corner represents a boot of that period. From that time until the reign of Edward III., the boots generally worn by the higher classes were ornamented profusely. During the reign of Richard II., the boots generally worn by the higher classes were ornamented profusely. During the reign of Richard III., the boots generally worn by the higher classes were ornamented profusely. During the reign of Richard III., the boots generally worn by the higher classes were ornamented profusely. During the reign of Richard III. the boots generally worn by the higher classes were ornamented profusely. During the beit of fastentiation of the control of the tooty to the state of the looty to the same, the other third to God, to Mahomet and his descendants, and to oryonans, pilgrims, and the poor. In the Raglish army of the green said that the went, were worn, and half-boots, with the reign of Edward VI., long boots, soming up to the knee, were worn, and half-boots, with the provent day, the victor's share is generally termed prize. According to the regulations concerning prize-

this reign, the long toes were banished attagether, short broad-toed boots took their place. These has covered the feet, and were made of kid leather, sine in order to show the coloured hose beneath. Henry VIII. and Elizabeth's reigns shacked shoes, others or namented with receives or gold and lace, were worn. This fashion obtained till the t Cromwell. Russet boots, coming close to the Russet boots, coming close to the with large stiff tops, then came into fashion. A fished leather protected the instep; and they were brigad toed and had thick, clumsy heels. Large, cumbrous boots were worn both by the royalists and roundheads. The courtiers of Louis XIV. wore very extravagant boots, with very wide tops, which were decorated with a profusion of costly lace. The dandies in Charles II.'s reign adopted boots of this kind, one of wtwise represented in the annexed illustration. Turing the reign of William III. shoes with high heels, broad toes, and large ties, were worn. Small buckles also came into fachion at the same time. The stiff jackboot, also represented in the engraving, was also intro-duced at this time. They were high in the heel, and the instep was covered with a large prece of leather, to which the heavy spur was fixed. They were only worn the instep was covered with a large prece of issuer, so which the heavy spur was fixed. They were only worn when riding, and all cavalry soldiers were furnished with them. The jack-boot may be considered the origin of the top-boot and all the other varieties of long boots now worn. Boots with yellow tops were much worn in the 18th century in England; and the duke of Orleans and other revolutionists, who affected aromaths with the English wore tom-books. the duke of Orleans and other revolutionies, war-affected sympathy with the English, wore top-boots ostentatiously. They are now only seldom work, except by hunters and jockeys. The Hessian boot superseded the top-boot; it was worn with tight pan-tuleons and was a very handsome leg-covering. The taloons, and was a very handsome leg-covering. The Hessian boot, which had a tassel in front, is represented in the illustration; as is also the Chinese boot, one of the strangest forms of foot-covering ever adopted. The soles are composed of many layers of thin flannel

The soles are composed of many layers of thin finned compressed together. The upper portions are made of a pliable but waterproof fabric.

BOOTY, boo'ts (Swed byte; Dan bytte), the specific taken from an enemy in war. The Greeks divided their booty among the army in common, reserving to the general only a larger shere. One of the prerogatives of a Grecian general was the distribution of the plunder taken from a vanquished enemy. We read in Momer that the valuable armour usually fell to the share of the leaders, whilst the common soldiers were resmitted. the leaders, whilst the common soldiery were permitted the teaders, whist the common soldiery were permitted to gather the spoils of the dead. Among the Lacedemoniaus, however, the soldiery were forbidden to plunder the conquered, although, in certain instances, a portion of the spoils was dedicated to the godr, whilst some other parts were reserved for the highest communders. After the battle of Plates, which took place 800 years subsequently to the Trojan war, the spoils of the Persians were regulated by the generals, who, after setting apart a portion for the decoration of the temples, shared the remainder amongst the soldiery. From that time the plunder was sold, the proceeds being applied to the decoration of the temples, as the additions and to the generals and their friends. to the soldiers, and to the generals and their friends. By the military discipline of the Romans, spoils taken from the enemy belonged to the republic, particular persons having no right to them. The generals, who piqued themselves on their probity, carried it intact to the public treasury. Sometimes, indeed, they divided it among the soldiery, to animate them, and to serve in lieu of reward; but this distribution depended

distribution issued in 1831, two prise-agents are nominated by letters of attorney, one of these agents being selected by the field officers, and the other by the sub-ordinate officers. The agents collect the booty, and, having converted it into money, they pay over the proceeds to the authorities. The persons who are entitled to share in this preparate are named by the contribution. titled to share in this property are named by the com-mander who has directed the expedition in which it was acquired. See further upon this subject, PRIZE.

BORACIO ACID, bo-rds'-sk (from Arish, bource, a species of mitre), (BO<sub>4</sub>),—This acid, which may be regarded as a teroxide of boron (see Bokon), is the only known-compound of oxygen and boron. It occurs is nature in certain volcanic districts, where it is a matter in certain volcanic districts, where it is many the acid, in internity of the desired the careful in internity of the stem. Succession from the earth in jets mixed with steam. In Tusoany, these jets, or funerolles as they are called, are conducted into artificial basins or small ponds. we conducted into artificial basins or small ponds. The boracic soid remains dissolved in the water, which is periodically removed, and evaporated in shallow leaden pans, which are heated by other fumerolles in the neighbourhood. During the evaporation, great quantities of sulphate of lime are deposited, which require removal from time to time. About 760 tone of crude boracic acid are annually exported from Tuscany. The crude acid is contaminated with 25 per cent. of sulphate of ammonia and alumina, and other saline impurities. Boracic acid is used principally for making borax, or biborate of sods. (See Borax.) Boracic acid is formed in the laboratory by dissolving purified borax in four parts of boiling water, and adding to the borax in four parts of boiling water, and adding to the hot solution a quantity of sulphuric acid, equal to onefourth the borax used. On cooling, boracic acid crysfourth the borax used. On cooling, boracic soid crystallizes out in pearly scales, containing three equivalents of water. These crystals contain a small quantity of sulphuric scid, from which they are freed by washing, drying, and fusing them in a platinum crucible. On redissolving the fused scid in four parts of water, and recrystallizing, it is obtained perfectly pure. Boracic seid, on being strongly heated, becomes anhydrous; and at a red heat it fuses into a transparent glass, which remains clear as it cools. It soon crumbles to pieces by absorbing water from the air. Boracio acid communicates to its compounds the property of fusibility; hence the use of many borates, more especially the biborate of soda, as fluxes. It dissolves in three times its weight of boiling water, but is very insoluble in cold. The solution is remarkable for possessing the properties of an alkali when tested with turmericpaper, which it changes to a deep brown. Even to litmus it only gives a slight reddish-purple tinge. When a solution of boracic acid is evaporated, a certain quantity of the soid rises with the steam; and this is the cause of the fumerolles described above as as the cause of the fumeroties described above as existing in Tuscany. Anhydrous boracic acid is but slowly volatilized by heat. It enters into combination with alkaline bases in several proportions, resembling silicia acid in this as well as in other particulars. A sexborate and triborate of potash have been obtained; and, although one contains six equivalents of acid and the other three, they possess the property of restoring the colour of reddened litmus like an alkali Boracic acid dissolves in alcohol, and burns with a characteristic green flame, with the exception of biborate of soda. The borates are not very important salts, and need not be alluded to here, further than to mention that, as a rule, alkaline borates are freely soluble, while those of the other bases are either inactually or very sparingly so. In 1867 the following quantity of borace acid was imported:—from Italy, 19,510 cwt.;—the computed value of which was £50,000.

Boractrs, bor-a-site, in Min., an anhydrous borate of magnesia, found at Luneberg, in Lower Saxony, and one or two other localities in that neighbourhood. to course in cubical crystals, and, when heated, pos-senses electric properties, the opposite angles of the cube being found to develop opposite forms of elec-

BORAGINACER, bo-raj'-i-nai'-se-e (froms borago, the name of the gen.), in Bot., the Borage fam., a nat. and. of dicotyledonous plants in the sub-class Corollifore, characterized by an overy deeply divided that four lobes, from the middle of which a single prises. The species are herbs or shrubs, with the leaves, usually rough with hairs. The flowers are regular and symmetrical; the calyx is persis-tent, and divided into either four or five segments; the corolla has the same number of lobes, and metally scales in the throat; the stamens vise from the corolls, are equal in number to its lobes, and alternate with them. The fruit consists of two or four distinct achania placed at the bottom of the persistent calyx. There are 54 genera, which include nearly 700 species, chiefly natives of the temperate regions in the northern bemisphere. Among them we find many well-known plants; such as the Forget-me-not, Borage, Comfresand Alkanet. (See Myosoris, Borago, Symputyme, Anchusa.) The various species are remarkable for ANCHUSA.) The various species are remarkable for their mucilaginous properties; some have roots which

are valuable dyeing agents.

BORAGO, bo-ra'-go (bor, for Lat. cor, the heart, ago, I cheer; because it was believed to exhibarate the heart, in Bot., a gen. of plants forming the type of the nat. ord. Boraginacea. The species B. offcinalis, commonly known as Borage, is now naturalized in England and most of the countries of Europe. but was at a remote period confined to Asia Minor. It is characterized by a wheel-shaped corolla with a It is characterized by a wheel-shaped corolla with a very short tube, the mouth of which is closed by scales; by five stamens with forked filaments, the inner arms of which support the anthers; and by these anthers being connivent around the atyle, in the form of a cone. The entire plant is rough with hairs, and has rather a coarse appearance; but its flowers are very beautiful, being of a fine blue colour. The round leaves were formerly always added to The young leaves were formerly always added to a cool tankard, or draught made of wine or cider, with water, lemon, and sugar. The flowers are used on the continent to ornament salads, and the tender tops are sometimes boiled in soups.

BORASSUS, bo-ras'-sus (Gr. borassos, the skin of the date), in Bot., a gen. of Palms, consisting of but one species, which is found in every part of India. This has been named B. flabelliformis, and is com-monly known to the European inhabitants as the Its stem attains a height of from 25 to Palmyra. 40 fect, and bears upon its summit a magnificent coronal of fan-shaped leaves. The fruit is about the coronal of fan-shaped leaves. The fruit is about the size of a child's head, and, when very young, contains a sweet pulp, which may be eaten. From the juice obtained from this plant, large quantities of an intoxicating drink are prepared by the natives. (See TODDY.) The fibres of the leaves are used for cord-Toppy.) The fibres of the leaves are used age, and the outer wood of the stem for bows.

Bonax, bor'-ax (Arab. haurac, a species of hitre), a compound containing boracie acid (which see) and soda. It was formerly imported from the East in soda. It was former, imported from the Lase to the crude state, under the name of timeal, which contained borar in combination with various substances of a saponaceous nature. It was purified by being heated with lime or soda until the whole of the sospy matter and other impurities were separated. Borax is now mostly prepared by fusing two parts of boracic acid, obtained from the Tuscan lagoous (ness Researc Acid), with one part of soda-ash. The BGRACIC ACID), with one part of suda-ash. The mixture is thrown on the floor of a reverberatory furnace, and heated until all effervescence has ceased. The fused mass is lixiviated and boiled until the impurities are precipitated : it is then decanted, and set aside to crystallize slowly. It crystallizes in rectangular hexagonal prisms, containing 10 equivalents of water. A new source of borax has lately been discovered in a deposit of borate of lime, occurring in the interior of Peru. Great pains are taken to crystallize the solution in regular crystals of a large size, as such only are marketable. Bofax is of great use in the aris as a flux. Having the property, when molted, of dissolving me-tallic oxides, it is used in soldering to clean away the film of oxide that would otherwise prevent the metals from uniting. It is sprinkled on the metallic surface, and melts with the solder. It is also used in gold and silver refining, and in making enamel, to render the compound more fusible. It is extensively employed in the manufacture of certain kinds of glass, and for fixing colours on porcelain and stoneware. To the chemist it is very valuable in blowpips analysis. (See Blowpips.) Borax may be made to crystallize in octahedral crystals, containing only 5 equivalents of water, by carefully evaporating a solution, of specific gravity 1 256, at a temperature between 133° Fah. and

## Borborians

174° Fah. Octahedral borax is preferred for soldering purposes, as, from containing less water, it does not intenseece so much as the ordinary prismatic form.

Bornonians, or Bornonians, bor-bo-ries, a sect of Gnostics, who arose in the 2nd century, and led very licentious lives, denying the doctrine of the last judament.

BORDARII, bor-dair'-i-i, a class of agricultural occupiers of land in this country, frequently mentioned in Domesday Book. They were distinct from the servi and villani, and seem to have been in a less servile condition, having abord, or cottage, with a small parcel of land, allowed to them, upon condition of their supplying the lord with poultry, eggs, or other small provisions for his board. They seem to have been a provisions for his board. They seem to have been a kind of cottagers, many of them being bound to render service to their lord in cutting wood, drawing water, threshing, and such-like; and, indeed, the term is often used to denote menial servants employed in such offices on an estate. According to Spelman, they were inferior to the villani, who were employed in the tillage of lands. Their condition probably differed on different manors. The number of bordarii in the different English counties noticed in Domesday Book is 62,634.— Ref. Ellis's General Introduction to Domesday Book.

Ref. Ellis's General Introduction to Domestay Book.

BORDER, THE, bor'-der (Ang.-Nor., the outer edge), in the earlier histories of England and Scotland, is applied to a large tract of debatable territory which lay between the two countries, the inhabitants of which were almost constantly at war with each other. Many a daring feat and many an heroic deed of these men have been celebrated in song and story, and furnished materials for numerous tales of fiction. There is a strange mixture of courage, bonour, and generosity, in the accounts transmitted to us of these border-flights. According to Froissart, Englishmen on the one party, and Scotsmen on the other party, are good men of war; for when they meet, there is a hard tight, without sparing; there is no hoo (i.e. cessation for parley) between them, as long as lay on each upon other, and when they be well beaten, and that the one party hath obtained the victory, they then glorify so in their deeds of arms, and are so joyful, that such as be taken they s all be ransomed ere they go out of the field; so that each of them is so content with other, that, at their departing, courteously they will say, 'God thank you.' But in fighting one with another there is no play nor sparing." The females also caught the warlike spirit of the times, and appear often to have mingled in lettle. In order to repress in some measure the turbul-nee of the people, as well as to maintain some show of regal authority over them, the guardianship of the border of each country was wardens of the norder of the reductive warden; intrusted to certain officers of bigh rank, entitled Wardens of the Morches. There were three marches in each country,—the East, West, and Middle; and generally each march had a distinct warden; but occasionally two of them were united under one. duties committed to the wardens were of a twofold character,-the maintenance of law and good order among the people under their juri-diction, and the protecting them from their enemies on the opposite border. Unfortunately the trust was usually confided to some person of great weight and influence within the jurisdiction, and they were too often private en-couragers of those disorders which it was their duty to suppress. During the reigns of Elizabeth and James VI., streamous efforts were made to repress the warlike spirit of the borderers; and after the union of the two crowns, peace was in some measure established. The most intractable of them were formed into a body of troops, and conducted by Bucclench to the Belgie wars. The border counties were disarmed, excepting such weapons as were retained by gentlemen of rank and repute; and the moss troopers, who continued to exercise their forner profession, experienced in great numbers the unsparing and severe justice of the end of Dunbar. In the civil wars of Charles L, the bor-derers resumed their licentious habits, particularly after the war had been transferred to Scotland; and the exploits of the moss-trooper shourish in the diaries and military reports of the time. In the reign of Charles II., we learn that they still existed, from the statutes that were directed against them; and it was

## Boro Buddor

only by the strict administration of justice which ful-lowed the legislative union of the two countries in 1707, that the marauding tendencies of the people were entirely represend.—Ref. Essay on Border Antiquities, by Sir Walter Soot.

BORDER-WAREANT, in the law of Scotland, is a war-

rant issued by the sheriff of a county, or the magistrate of a royal burgh on the borders, for the apprehension of a person who has incurred debt in Scottand, but who is resident in England. It is granted on onth being made to the debt; but in practice these warrants. are now little used.

BORDURE, bor'-dure (Fr. bord, the edge, coast), in Her., a narrow space, running round the edge of the shield, and properly containing the fifth part of the whole field. It was originally used as a mark or our-ference, to distinguish different branches of the same varied, according to the different forms of lines of

division and boundary used in heraldry.

Bone, bor (Aug. Sux.), in Mil., the cylindrical cavity of any weapon used for the projection of shells, shot, bullets, or any missiles of a similar nature. The fowling-piece and the soldier's old weapon, "Brown Bess," are termed smooth bores, in contradistinction to fire-arms with rifled or grooved barrels. Formerly, the bore of cannon and guns of every description was cylindrical; but in the Lancaster gun an oval form is adopted, and in the Whitworth gun the bore is polygonal. In the Entield rifle and Armstrong gun there are a number of grooves twisting spirally along the interior surface of the barrel. The operation of boring cannon and gun barrels is one requiring great care and nicety, and is effected by the rapid revolution of a steel tool called a cutter, attached to a shaft which is turned by machinery; sometimes the gun itself is made to revolve while the boring-tool remains stationary. In guns that are cast hollow, or made of metal rods welded together on a core like the Armstrong gun, boring is necessary to bring the whole length of the interior to a uniform calibre. From 1750 until of late years, cannon were cast in a solid mass, and the interior cavity bored afterwards. The word bore is sometimes used in a similar sense to "calibre," to denote the diameter of the in-

BORER, bor'-er, a name given to many very small electricous insects of the genus Phinus. Their name colcopterous insects of the genus Ptimus. is derived from the fact that their larvæ, small white muggots, cat their way into old wood, &c., by means of strong cutting jaws, called maxilla. These holes, which they are constantly making in old furniture, have all the appearance of having been produced by a fine gimlet or drill. After working its way into the wood, the borer fills up the drill-hole in its passage with a fine powder, and forms a cocoon, from which it afterwards emerges in the form of a small winged beetle. The Anobiam tesselatum, one of the same genus, is re-markable for a loud ticking noise which it makes at night, and which has gained for it the title of the Death-watch. The Anohum striatum is also remarkable for the persistent way in which it simulates death.

BORING, bor'-ing, the act of perforating or making a hole throughout the entire length or thickness of a solid body. It is a term most usually employed to designate the processes used in sinking artesian wells (which sec), in seeking for minerals, and in perforating wood in carpentry, as well as metal, in the manufac-ture of guns and tubes. The application of the process, in so far as it relates to the boring of cannon and of cylinders for the steam-engine, will be treated of elsewhere. (See CANNON, CYLINDER.)

BORING THE TONGUE, like nailing the ear, pinching the nose, branding the cheek or forehead, was a species of punishment anciently inflicted in Scotland criminals, but which has now long ceased. The last of the kind on record is that of Jean Spance, a notour (i.e. notorious) thief, who was sentenced in 1728 to be pilloried, her lug (i.e. car) mailed, and her nose pinched.

Boro Buddon, bus-o bust-dos, a temple in Java, of
most claborate construction, decicated to Buddha
(see Buddunism), remarkable the hoing the finest speccimen of Buddhist prehitecture that is known. building is supposed to have been erected in the 14th century. It is pyramidal in form, rising from a square base, the sides of which are 400 feet in length. The

#### Boroffworie Acid

façade of the base is ornamented with a continuous bas-relief, in which various occurrences in the life of Siddhartha, the founder of Buddhism, are represented. The base itself is about 16 feet in height, and forms a terrace from 40 to 50 feet in width, to which access is obtained by flights of steps. On this platform five successive terraces, varying from 8 to 12 feet in height, and from 16 to 20 feet in breadth, rise one above another. On the edges of these terraces a great number of pinnacles and cupolas are built, the larger cupolas forming as many as 436 arched niches, in each of which a statue of Buddha, of life size, is placed. The spaces between the hiches are filled up with bas-reliefs of the same nature as those which surround the base. The ornamentation of the inner sides of these rows of buildings is more diversified, and of greater minuteness in detail, than that on the outside. On the fifth ter-race, which is square, corresponding in form to the base, three more, circular in form, are built, on which are placed at intervals 72 small domes, each containing a statue of Buddha. On the top of this huge terraced pile there is a dome, about 40 feet in diameter, sur-mounted with a spire; and immediately beneath it a sort of pit, or sunken chamber, 10 feet in depth, which is supposed to have contained some relic of Buddha.—

Ref. Fergusson's Handbook of Architecture.

Borofluoric Acin, bor-o-flu-or'-ik, or Fluoboric Acid, as it is generally called, is formed in combination with potassium by saturating hydrofluoric with borncie acid, and neutralizing by carbonute of potush. The compound is washed, dried, and heated with an equal weight of potassium. Borofluoride of potassium is

used in the preparation of boron.

BOROTHME'S HARP, bo-ro-cem'. - This ancient musical instrument formerly belonged to the great Irish monarch Brish Borothme, who met his death at the battle of Ciontari, A.D. 1014, when it descended to his son and successor Donah. The latter prince being deposed soon after by his nephew (whose father he had assassinated), fled to Rome, taking with him his harp and crown. These relies were kept in the Vatican until and crown. who soon after presented it to the first earl of Clanri-carde, in whose family it remained until the beginning of the 18th century, when it passed through a female branch of the De Burgha to the MacMahous of Glenagh, and thence into the possession of Counsellor Macna-mars of Limerick. In the year 1782 it was presented mars of Limerick. In the year 1782 it was presented to the Rt. Hon. William Conyngham, by whom it was deposited in Trinity College Museum, where it still remains. This curions instrument is about thirty inches in height, and richly ornamented, the sounding-board being of oak, and the arms of red sally. It contains a large crystal set in silver, under which was formerly

another stone, which is now lost.

Boron, bor'-on, in Chem. (symbol B, equivalent 10'9), a combustible element, closely allied in its properties to carbon and silicon (both of which see). In nature it occurs in combination with oxygen, in the form of boracic acid, in a few localities. It was first obtained by Davy in 1808, by submitting moistened boracic acid, inclosed between platinum plates, to the action of the voltaic current. A brownish substance appeared at the negative pole, which, conceiving to be a metal, he termed boracium. By further experiment he proved it to be a non-metallic body, resembling carbon in its properties, and altered its name to borm It was, however, but imperfectly known until Thenard and Gay-Lussac obtained it more readily by heating boracic acid with potassium. The metal combined with the oxygen of the acid to form potash, which was washed away with water, leaving the boron behind. A still more ready method of preparing it is by heating mixture of potassium and borofluoride of potassium in an iron crucible. Boron and fluoride of potassium with a weak solution of chloride of ammonium. Beron thus prepared is a brownish-green powder, dissolving slightly in water, forming a yellowish-green solution. It is rendered insoluble by being heated in close vesseis; its specific gravity being at the same time shinged from 1-183 to 1-844. It suffers no change, constructions of the construction of the construction of the method of the construction of the constructi

# Borough-English

electricity. Alkalies and acids (except nitric sold) produce no effect on it. Nitric acid converts it into boracic acid. It does not decompose water at any temperature, and is constant under the action of air or oxygen until the temperature reaches 600°, when it or oxygen until the temperature reaches 600°, when it burns belliantly, forming boracic acid by the absorption of oxygen. Prepared in the above way, boron is amorphous; but. MM. Deville and Wöhler have obtained it in garnet-red transparent crystals, by fusing boracic acid with 80 per cent. of metallic aluminium in a propagation former. a powerful furnace. The crystals are extremely hard, scratching sapphire and corundum, and yielding only to the diamond, which is generally injured by the operation. Crystallized boron has never been fused, and resists the action of oxygen at very high tempera-tures. Boron is obtained in a graphitic form when borofluoride of potassium is decomposed by aluminium. It bears a close relation to the graphitic form of car bon, or ordinary graphite. Boron combines with several elements, forming borides with the metals. The close relation always supposed to exist between boron and carbon has been curiously confirmed by the fact of both of these elements being capable of assuming the amorphous, crystaline, and graphitic forms. The only important compound of boron is boracio acid

BORDUGH, bur'-o (Fr. bourg; Lat. burgus; Sar. borhor).—A borough is a city or other town that sends burgesses to parliament. (1 Bl. Com. 114; Litt. 8, 164; Co. Litt. 108 b; see also Roform Act, 2 Will. IV. o. 45, s. 79.) The word, however, was originally used in a more extensive sense. (See Co. Litt. by Harg. 108 b, n. (4).) In Jacob's Law Dictionary, v. Borough, the term is taken to mean a town sending burgesses to parliament, and not being a city. But see the anthorities first cited; also Co. Litt. 109 a. In the Municipal Corporation Act, 5 & 6 Will. IV. c. 76, "horough" is used in a sense peculiar to that statute, and expresses a corporate town, whether sending representatives to parliament or not. Among our Saxon and Norman ancestors, all places which were colled horoughs were fonced or fortified. In the reign of Henry II, they had great privileges. If a bondman or servant remained in a borough a year and a day, he was by that residence made a free man - (Glance.) Why these were called free burghs, and the tradesmen in them. free burgesses, was from a free-lom to buy and sell, without disturbance, exempt from toll, &c., gramed by charter. Parliament boroaghs were generally by charter, or towns holden of the king in ancient demesne.—(Brady.) Erglish boroughs first sent representatives to parlyament in the reign of Henry 111., 1265. Burgesses were first admitted into the Scottish parliament by Robert Bruce, in 1326, and into the Irish in 1365.—For an account of the rise and progress of boroughs and other numicipal jurisdictions in Europe, consult "A View of the Progress of Society in Europe." in the Introduction to Robertson's Charles the Pfil. and The History of Civilization in Europe, by Guirot.

Borough was the name also given to a certain division of land under the Saxon kings. A borough or tithing comprised a district containing ten beads of timilie and ten tithings constituted a bundred. The head man of the borough was called the borough-head, headborough, borsholder, or tithing-man, and was answerable for the conduct of people of his borough. The ten householders of the horough formed a corporation, of which the headborough was president; and no man was allowed to reside above torty days in England without being enrolled in some boyough. (See TITHING.)

Borovgs, in Scotland. (See Pungal)

BOROUGH-ENGLISH (Sax. backer Englise) is a customary descent of lands (formerly held in uncient burgage) to the youngest son, or, if the owner harh no issue, to his younger brother, and extends to col-laterals in some instances. The custom prevails in several cities and ancient boroughs, and districts of smaller or larger extent adjoining to them, in different parts of the kingdom, and governs the descent of copyhold land in various manors. It is called horough-English in contradistinction, as it were, to the Norman customs, and which is taken notice of by Glanvil. lib. 7, c. 3, and by Littleton, s. 165. The reason given the thattery. Like silicon, it is a non-conductor of by Littleton is, because the younger son, by reason of

## Borough Fund

his tender age, is not so capable as the rest of his bre-thren to help himself. Other authors (3 Med. Rep. pref.) have, indeed, given a much stranger reason for this custom, as if the lord of the fee had anciently the right of concubinage with his tenant's wife on her wedding night; and that therefore the tenement descended notto the eldest but to the youngest son, who was more certainly the offspring of the tenant. Bus it is not known that ever this custom prevailed in England, though it certainly did in Scotland (under the name of mercheta or mercheta) till abolished by Malcolm III.; and perhaps a more rational account than either may fetched (though at a sufficient distance) from the practice of the Tartars; amongst whom, according to Father Duhalde, this custom of descent to the young-est son also prevails. That nation is composed totally of shepherds and herdsmen; and the older sons, as soon as they are capable of leading a pastoral life, migrate from their father with a certain allotment of cattle, and go to seek a new habitation. The youngest son, therefore, who continues latest with the father, is naturally the heir of his house, the rest being already provided for; and thus we find that among many other northern nations it was the custom for all the sons but one to migrate from the father, which one became his heir. — (Walsing. Upodiam. Neust, c. ].) So, possibly, this custom, wherever it prevails, may be the remnant of that pastoral state of our British and German ancestors which Cassar and Tacitus describe.

Ref. Third Real Property Report, p. 8; Year-Book, 36 Hen. VI. 20; Co. Litt. by Hargrave, 10 a, n. (3), n.

Borougu Fund is a fund instituted by the Municipal Corporations Act, 5 & 6 Will. IV. c. 56, which declares that the rents and profits of all hereditaments the interests, dividends, and annual proceeds of all moneys, dues, chattels, and valuable securities, belonging to the former body corporate of such borough named in the schedules A and B, or to any member or officer thereof in his corporate capacity, and every fine and penalty for any offence against this act, the application of which is not otherwise therein provided for, is to be raid to the treasurer of the borough, and to be carried by him to the account of a fund to be called "the Borough Fund." After the payment of all the lawful After the payment of all the lawful debts due by the late body corporate, this fund is to be applied towards the payment of the salary of the mayor, and of the recorder, and the police magistrate (where the latter functionaries shall be created), the malaries of the town clerk, treasurer, and every other officer appointed by the council; and other borough expenses specified in the act.

BOROUGH MATE is a rate levied within a borough by order of the council of the same, in terms of act 5 & 6 Will, IV, c. 56, which declares that when the borough fund shall not be sufficient for the purposes aforesaid, the council of the borough is hereby authorized and required from time to time to estimate, as correctly as may be, what amount will be sufficient for the payment of the expenses to be incurred; and in order to raise the amount, the council is authorized and required, from time to time, to order a borough rate in the nature of a county rate, to be made within their borough, for which purpose the council shall have all the powers within their borough that justices of the peace, assembled at their general or quarter sessions, have within their jurisdiction. Persons considering themselves ag-grieved by the rate may appeal to the recorder at the pext quarter sessions for the borough : or, in the case of no recorder within the borough, to the justices at the next quarter sessions for the county.

Bornellians, bor-rel'-li-ans, a sect of Christians in Holland, so called from their founder, Borrell, who was a man of some learning, particularly in the Greek, and Hebrew languages. They reject all public acts of worship, public prayer, and the use of the sacraments. They assert that the Christian churches have degenerated rated, because they have suffered the Word of God. which is infallible, to be interpreted by fallible men. They are said to lead austere lives, and to devote a considerable portion of their goods to charity.

from April. In this view they were to be characterized by wind, ruin, snow, and aleet; and the broken weather that usually prevails about that time gave some colour to the notion.

BORSHOLDER. (See BOROUGE.) Bos. (See Boving.)

Boszesman, boszes-nda (Du., bush-man), an exceedingly diminutive variety of the Hattentot race, perfectly uncivilized and very savage in disposition. They inhabit that portion of Africa which lies north of Cape Colony. Some individuals of this tribe were arbitistical in this country of females and the were

Cape Colony. Some individuals of this tribe were exhibited in this country a few years ago.

Roskor, bos'-koi (Gr., the grazers), was the name given to a class of ascetic monks who lived in Syria and Mesopotamia, and are said to have subsisted solely upon roots and herbs. They did not inhabit any house, and professed to spend their time in the worship of God, in prayers and hymns.

Rose Loss (Fr. hosse) in Arch., an ornamental pro-

Boss, toss (Fr. bosse), in Arch., an ornamental projection covering the intersection of wooden ribs that cross each other, generally at right angles, dividing the surface of a flat or

vaulted ceiling into compartments. The boss is often beautifully carved into foliage or fretted work. and cometimes shields with armorial bearings are introduced, and representations of the human face, and heraldic emblems. It is most frequently introduced in quently buildings belonging to the Decorated English and

BOSS.

Perpendicular English styles of architecture. name is also given to the projection sometimes found in the centre of a shield.

BOSTANJI, bos'-tan-ye (Turk. bostan, a garden), lite rally signifies gardeners, but is applied to a class of men in Turkey who, in addition to acting as the sultan's gardeners, perform a variety of other functions, such as mounting guard in the scraglio, rowing the sultan's barge, and attending on the officers of the palace. Their head or chief, the bostanji-bashi, is one of the grand dignitaries of the empire; he has the rank of a pasha, is governor of the seraglio and the other imperial rosidences, steers the suitan's barge, and has the jurisdiction of the shores of the Bosphorus and the Sea of Marmera. This office is only conferred upon personal favourites of the sultan. The bostanji, at one time, amounted to 5,000 men, but at present their number does not exceed 600. They formerly did military duty in the field with the janissaries, and in war their strength was raised to 12,000 men.

Boswellia, tos-well-li-a, in Bot., a gen. of plants belonging to the nut. ord. Amyridacea. The most important species is *E. tharifera*, a tree which grows to a large size, in hilly situations, from the Coromandel coast to the central parts of India. This plant is the source of the valuable gun-resin known as Indian olibanum. (See OLIBANUM.) B. papprifera, a native of Abyssinia, also yields a fragrant gum-resin, and is further remarkable on account of its inner bark, which

peels off in thin white layers like paper. BOTANY, boil-di-ne (Or. botane, an herb), that part of natural history which relates to the vegetable kingdom. In its widest sense, botany comprehends all that is known of plants, and, therefore, forms a boundless field of inquiry. The student has to consider the external configuration of plants,—their structure, the functions which they perform, the relations which they bear to ach other, and the uses to which they are subservient. Many are deterred from studying botany by a miscon-ception of its scope and nature. Imagining that its ception of its scope and nature. Imagining that its sole object is to name and classify the various vegetable productions of the globe, they conclude that the study is confined to the acquisition of certain dry details and a vocabulary of hard words. Eighty-four years ago, some time before the natural system of Jussien was considerable portion of their goods to charity.

Bornowing Days, bor-re-ing, in the popular and Editorial temperature markable man, Gibert White of Equities of Scotland, and some parts of England, is schooled, alluded to this misconception, and clearly the name given to the last three days of March, from the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken the popular notion that they were borrowed or taken м 2

## Botany

"has always been, that it is a pursuit that amuses the fancy and exercises the memory, without improving the mind or advancing my real knowledge; and where the science is carried no farther than a mere systematic classification, the charge is but too true. But the botanist that is desirous of wiping off this aspersion should be by no means content with a list of names; he should study plants philosophically, should investigate the laws of vegetation, should examine the powers and virtues of efficacious herbs, should promote their cultivation, and graft the gardener, the planter, and the husbandman on the phytologist. Not that system is by any means to be thrown aside,—without system, the field of Nature would be a pathless wilderness,—but system should be subservient to, not the main object of, pursuit." To facilitate investigation, Botany has been divided into several departments, which may be regarded as separate sciences. The objects and scope of each of these sub-sciences will now be

explained.
1. Structural Botany, or Organography, includes everything relating to the organization of plants. It describes the different kinds of tissue which enter into the composition of plants; it explains the structure of every organ; and it also teaches the relation that one organ bears to another. That branch of structural botany which has reference to the elementary tissues is sometimes distinguished as Venetable Histology. The microscope has shown that the various tissues are composed of little membranous sacs or vesicles, varying in form and size, and united in different ways. (See CELL.). The study of these elementary organs cannot be prosecuted without the aid of costly instruments, but much may be learned from the clear descriptions and excellent illustrations given in modern botanical works, particularly those of Lindley, Balfour, and Bentley. Some plants consist of simple cells only, which continue throughout life to produce new cells, and to perform all the vital functions. A flowering plant, however, although originally cellular, produces organs composed of cells and vessels, variously modified and arranged, and covered by an epidermis (which see). These compound organs may be divided into nutrities, or those concerned in the nourishment of the plane, and reproductive, or those which are employed nume, and reproduction of those which are employed in the production of new individuals. The former are the stem, root, and leaf; the latter, the flowers and fruit. (See these words, also Ovulle, Pistriu, Sero, STAMEN.) Leaves occupy various positions on the stem and branches, and their arrangement forms a subjust for special state. subject for special study. (See Phyllotaxis.) arrangement of flowers on the floral axis and its ramifications, has also to be considered. (See Thypothesence.) The term Morphology has been applied to that portion of Organography, which treats of the abnormal modifications of the different organs. The researches which have been made in this department during the last forty years, have confirmed the doctrine advanced by the German poet Gothe, namely, that all those parts familiarly known as leaves, flowers, and fruit, are constructed on a simple uniform plan, out of one kind of organ in different states of modification and combination; and that there is no other difference between the flower of a rose and that of a nettle, than what arises from modifications and combinations of this typical organ, which is the leuf. elecidating this doctrine of the unity of type, which constitutes the basis of the theory of botany, Lindley says, "We are so accustomed to talk of plants bearing leaves, and flowers, and fruit, and it is so evident to our senses that extremely different organs do exist under such names, that it seems inconceivable that parts so very dissimilar should be only leaves in dif-ferent states; that the pure white petals of the fily, the rich red flowers of the rose, the sweet-smelling blossoms of the jusmine and orange, or the long trumpet-shaped corollas of the honeysuckle, should all be leaves; that the stamens in which the fertilizing powder is locked up, the pistils which are destined to receive the infinence of the pollen, the ovula that they contain, and finally, that the fruit which is the result of the action of the two last, are all so many parts formed out of one common organ, which in a particular and very frequent state is what we call a leaf. Botanists do not

# Botany

or a peach, is in a state of mental delusion, and that while he fancies himself to be enjoying the pleasure of gratifying his palate by the most delicious flavours, he is really only chewing the leaves of these plants; they assert that those appendages of a plant which are commonly called the leaves have a peculiar anatomical structure, and a certain relation to the stem on which they are borne, and, being developed according to certain fixed laws, are always arranged upon a certain and uniform plan with respect to each other; and that and the other organs, whether calyx, corolla, stamens, pistils, or fruit, have an anatomical structure essentially the same, bear the same relation to the axis that they grow upon, are developed according to the same laws, are arranged upon the same certain and uniform plan with respect to each other, and, finally, are constantly becoming transformed into leaves of the ordi nary appearance; thus losing the condition in which they are usually found, and reverting to their structural type." Morphology is a most attractive subject for Morphology is a most attractive subject for study, but less important in a practical point of view than that part of Organography which has reference to the ordinary forms of organs, and the manner in which they are arranged. No systematic arrangement can be understood without a knowledge of the laws upon which the symmetry of plants depends, and a practical acquaintance with the structure of every kind of organ.

2. Physiological Botany treats of plants in a living or active state, and of the manner in which their fund tions are performed; it explains how they are influenced by the several agencies of light, heat, air, and moisture; and it describes their various secretions and the nutriment afforded by the soil. It need searcely be said that any attempt to investigate the laws of vegetable life would be abortive without a perfect acquaintance with the more important details of organization. Plants, not being endowed with voluntary motion, derive their food either from the soil in which they are fixed, or from the atmosphere by which they are surrounded. The nutriment, consisting of water, generally holding salts in solution, is absorbed, by the aid of endosmose, by the extremities of the root. then passes from cell to cell, and ascends the stem, dissolving, in its course, some of the organic matter stored up in the vegetable tissue. Arrived at the green shoots and surfaces of the leaves, which are covered with minute openings, or stomato, the sap is exposed to the influence of light, heat, and air. About twothirds of the moisture taken up is now evaporated and exhaled; the remainder, which, of course, becomes thickened, undergoes certain chemical changes, and then begins to descend by the under-surface of the leaf, and along the bark. It takes either a direct or a circuitous course downwards, communicating with the centre of the stem by the medullary rays, depositing various secretions, more especially in the bark, and giving origin to substances which are destined to nourish and form new tissues. Finally it reaches the extremity of the root, where absorption had commenced; a small portion is there exercted, while the remainder mixes with the newly-absorbed fluids, and again circulates in the sap. (See Sar, Endosmose, Secretions.) The circulation of the sap has been adduced as an example of the vital processes elucidated by physiology, because it is due to the combined action of all the organs of putrition, and may therefore serve instead of several illustrations. The study of the instead of several illustrations. The study of the special functions of the various organs necessarily precedes that of the general physiological phenomens, each as circulation, assimilation, respiration, fertilization, and germination. Under the names of the different organs of nutrition and reproduction, the reader of this work will find full particulars respecting their functions. The physiology of reproduction is treated of at length under the heads Pollen and Embryo.

3. Systematic Botany, or Turonomy.—This department metudes the principles of classification, which

of the jasmine and orange, or the long trumpet-shaped corollas of the honeysuckle, should all be leaves; that the stamens in which the fertilizing powder is locked up, the pistils which are destined to receive the influence of the pollen, the ovula that they contain, and, finally, that the fruit which is the result of the action of the two last, are all so many parts formed out of one common organ, which in a particular and very frequent state is what we call a leaf. Businest do not not successfully and arrange plants in such a manner that the botanist may readly ascertain the name of any specimen, and arrange plants in such a manner that the botanist may readly ascertain the name of any specimen, and are the same time, get an insight into its true nature

and general properties. When it is considered that there are some 120,000 known species of plants, it is obvious that there must be a definite nomenclature and classification, were it only to facilitate reference and communication. Before plants can be classified, their peculiarities of structure must be clearly defined hence the necessity of the technical language which is employed in descriptive botany. This language ought not to deter the lover of nature from studying the principles of classification; for, in acquiring a know-ledge of the numerous technical terms, he will, at the same time, fix in his mind the ideas which they represent, and thus, in reality, become acquainted with unportant elementary facts. Botanists are blamed for using so many hard words; but it should be rememhered that they have to explain very minute points of structure, and must employ a language more rigorously defined than that of ordinary conversation. Botany," says Dr. Hoefer, "would be the most lovely of the defined than that of our says Dr. Hoefer, "would be the most lovely of the sciences, if botanists had not made its nomenclature so dry and repulsive. All the world would study it, if it was addressed less to the memory and more to the intelligence." The remarks of Mr. Page on the use of technical terms in geology may be fairly set in oppo-sition to the observation of the French writer:— "Scientific terms, when once thoroughly compre-hended, are quite as easily remembered as those derived from the language of every-day life; while, being chiefly compounds of Greek and Latin, they constitute a nomenclature intelligible to the scholars of every country. There is nothing more perplaxing than a nultiplicity of local and previncial terms; and one can easily imagine the confusion and obstruction that would arise were every country and district adhering to its own vernacular, instead of adopting a uniform system of terminology. The technicalities of science, often so ignovantly inveighed against, are, in fact, the instruments by which it effects its progress. New objects require new names, and new facts new phrases to express their relations; and the sooner the stu-dent can make himself familiar with those terms and their applications, the more rapid and pleasant will be his onward progress." That part of Systematic Botany which relates to the technical language of the science is sometimes called Glossology. The principles of classification constitute what is properly called Taxonomy, though this term is often applied to the whole department. There have been two great plans pro-posed for the classification of plants, one denominated artificial, and the other natural. The first is founded on characters taken from certain parts of plants only, without reference to others; while the second takes into account all the parts of plants and involves the idea of affinity in essential organs. In both artificial and natural systems, the lower divisions, namely the genera and species, are the same, the great difference between them consisting in the manner in which the genera are grouped into orders, and the orders into classes. (See Species, Genus, Orders, Class.) The plants in one of the higher divisions of an artificial system, such as that of Linnens, have no necessary allinity, and are connected only by certain characters, more or less superficial, which have been selected as the signs of that division. Such a system may, therefore, be compared to a dictionary, in which words are arranged, for convenience of reference, in alphabetical order, adjacent words not necessarily agreeing with each other, further than in commencing with the same letter. In a natural order, on the contrary, all the genera will be found to have a true family likeness; for their association is the result of a careful consideration of the structure of every organ. The classes in the natural system have been formed upon the same principle, by uniting orders which possess many important characters in common. The Lineman system leads to little more than a knowledge of names, and can only be looked upon as an index to the genera. superior to every artificial scheme previously promulgated, its day has gone by, and the more philosophical system has taken its place. Linnsus himself never intended it to be anything more than a provisional arrangement, and distinctly stated that a natural method was the great object of scientific inquiry. The general principles of the Linnaau, or Sexual system, may be explained in a few words. Twenty-four classes

are founded on the number, position, relative lengths and connection of the stamens; while the orders in these classes depend on the number of styles, the nature of the fruit, the number of the stamens in the classes where this character is not used for distinguishing them, and the perfection of the flowers. twenty-fourth class includes plants having inconspicu-ous flowers, and in it the orders are formed according to natural uffinities. Under these classes and orders, all the known genera and species are arranged. Even as an artificial method for discovering the names of plants, the Linnean system has many imperfections. Being based upon the more obvious characters of the reproductive organs, it cannot be of the least use when the plants are not in full flower, with all the stamens and styles perfect. The different flowers on the same plant often vary as regards the number of the stamens. Again, if the classification were carried out rigidly, it would separate, in many instances, the species of the same genus; but so sensible was Linnaus of the importance of maintaining the natural obstactor of his genera, that he sacrificed the symmetry of his scheme for the sake of keeping all the species together. natural system of classification is based upon the real affinities of plants, and necessarily takes into account all the organs. Though it can never be perfect until all the plants of the globe have been examined, it has already reached a very high point of develop-ment, and a great number of the orders which have been determined are quite as natural as the orders or differential the quite as natural as the orders in the animal kingdom. For example, those groups of plants designated as Ranunculacea, Gentianacea, and Atropacea, are as distinct in their characters as those animal groups named Cetacea, Cheiroptera, and Rodentia. (Nee Animal Kingdom.) Such being the case, it follows that a knowledge of one species is to a great extent the knowledge of many; for an indi-vidual, if well selected, will exhibit the most important characters of all the other plants in the same natural group. Thus, by studying the comeon radish (see RAPHANUS), or the mustard (see SIMARIS), the botanist may obtain a general knowledge of about 1,600 species which constitute the order Crucifera, and which are all formed, as it were, on the same type. The properties of plants accord in a very remarkable manner with their structure; and, as a general rule, the position of a plant in the natural arrangement indicates its proa plant in the natural arrangement indicates its properties. For example, if a botabist, on examining a plant, fluds all the structural peculiarities of the order just mentioned, he may feel confident that it is not poisonous, but most likely abaseorbutic or pungent, It, however, he should meet with one of the Atropaces, he might safely set it down as a plant possessing poisonous narcotic properties. Enough has been said to prove that the natural system is much more than a mere index to the names of plants. It reveals to a certain extent the plan of creation, and is at once an aid to research and a record of discovery. schemes based upon the natural affinities of plants have been devised. These may be regarded as so many versions of the one true system; for, though they have been worked out by different methods, they agree in nearly all their grand divisions. The characters by which the primary groups have been determined are furnished by the elementary tissues, and the most important organs of vegetation and reproduction. Regarding only the elementary structure, plants may be arranged under the heads of Cellulur and Voscular, according to the absence or presence of regular vessels. (See Tissue, Cell, Vessel.) A more satisfactory arrangement results from a consideration of the different modes by which plants are propagated. Some spring from true seeds, containing the radimentary organs called cotyledons; while others are developed from spores, in which no distinct organs can be traced. The former are said to be cotyledonous, and the latter acotyledonous (i.e. without cotyledons). As the number of cotyledous forms a natural distinctive character, the or coverage orms a natural asserted character, one first group of plants is subdivided into monocolfield-nons, having one cotyledon, and dicotyledonous, having two cotyledons. The mode in which the root is produced affords characters which confirm this arrangement. The young root of an acotyledon is heterophizal, but of a magnetical and that of a that of a monocotyledon is endorhizal, and that of a dicotyledon exerbizal. (See EMBRYO.) The three The three

### Botany

groups are further characterized by the stems; those of the first being acrogenous, those of the second endogenous, and those of the third exogenous. (See STEM.) Stemless plants are said to be thallogenous, and form a distinct section of the acotyledonous group. The venation of the leaves establishes the same great natural divisions; and similar results are obtained from a consideration of the flowers; monocotyledons and dicotyledons being phanerogamous, or flowering, and acotyledons tryptogamous, or floweries. The following table exhibits the relation of the different characters:

Embryo, Reticle. Stem. Flower.
Acctylede- Heterorhizal Acrogenous Cryptogamous.
Monocoty- Endorhizal Endogenous PhanerogaDiootyle- Diootyle- donous. Exorhizal Exogenous

The arrangement adhered to in this dictionary is that adopted by Professor Bentley in his excellent. Manual of Botany." It is founded upon the schemes of Jussieu, De Candolle, and Lindley, and may be thus described:—The vegetable kingdom is divided into two sub-kingdoms,—Phanerogamia, flowering or cotyledonous plants; and Cryptogamia, floweriess or acotyle-donous plants.

## Sub-Kingdom PHANEROGAMIA.

Plants which have evident flowers, and which are propagated by seeds containing cotyledons.

#### Class I .- DICOTYLEDONES.

Embryo dicotyledonous; germination exorhizal; the stem exogenous; leaves with reticulated venation; flowers with a quinary or quaternary arrangement. In this class there are two great divisions:—

Division 1. Angiospermia.—Ovules inclosed in an ovary, and fertilized indirectly by the action of the pollen on the atigma. In this division there are four sub-classes:—

Sub-Clear 1.—Thalamiflorie, or plants with flowers usually furnished with both calvx and corolla, the latter composed of distinct petals inserted on the thalamasis stamons hypogynous, or adherent to the sides of the overs

Sub-Class 2.—Calycifore, with flowers having usually cally and corolla, the latter mostly with distinct petals and inserted on the cally; stamens either perigyrous or epignous. This sub-class is divided into—1. Perigyrae, in which the cally is free, or nearly so; the stamens usually perigyrous, and the ovary superior. 2. Epignae, in which the cally is more or less adherent, and the ovary inferior.

Sub-Class 3.—Corollifora, flowers having both calyx and corolla, the latter with united petals; stamens inserted on the corolla or ovary, or free and axising from the thalamus. Sub-divisions:—L. Epigpaa, in which the calyx is adherent, and the ovary consequently inferior. 2. Hyposlandna, in which the stamens are inserted into the thalamus, and do not adhere to the corolla; ovary superior. 3. Epigetala, or Epigovolla, in which the corolla arises from the thalamus, and has the stamens attached to it; ovary superior.

Sub-Class 4.—Monochlamydex, or Apetelx, flowers having either a calyx only, or without both calyx and corolla.

Division 2. Gymnospermia.—Ovules maked, or not inclosed in an ovary, being fertilized directly by the action of the pollen.

## Class II .- MONOCOTYLEBONES.

Embryo monocotyledonous; germination endorhisal; stem endogenous; leaves usually with parallel seriation; flowers with a ternary arrangement. In this class there are three sub-classes:—

Sub-Class 1. Dietyogene. Leaves with a reticulated venation, decidions; rhizome and root with the wood arranged in a concentric manner; floral envelopes verticilists.

Sub-Class 2. Petaloida of Florida.—Leuves with a parallel venation, permanent: floral envelopes (perianth) verticillate, and usually coloured, rarely sculy sometimes absent. Eubdivisions:—1. Epigyna, in

#### Botany

which the flowers are usually hermaphrofite; perianth adherent; ovary inferior. 2. Hypogynm, with flowers usually hermaphrodite; periauth free; ovary superior. 3. Diclines, in which the flowers are usually unisexual; perianth either absent or consisting of a few scales.

Sub-Class 3. Glumacea.—Leaves parallel-veined, permanent; flowers glumaceous, that is, having no proper perianth, but consisting of imbricated bracts.

# Sub-Kingdom CRYPTOGAMIA.

Plants which have no flowers, and which are propagated by spores. This sub-kingdom constitutes a class by itself, viz.

#### Class III .- ACOTYLEDONES.

Other characters besides those which define the subkingdom may be enumerated. The germination is indefinite or obscure; the stem is sometimes present and sometimes absent,—in the former case, when woody, it is acregenous; the leaves, when they exist, have forked veins; no true flowers are produced. There are two sub-classes:—

Sub-Class 1. Acrogena. — Plants with stems and leaves distinguishable, and possessing stemata.

Sub-Class 2. Thallagence. - Plants with no distinct stems or leaves; stomata absent.

For a full explanation of the above classes and subclasses, the reader is referred to the separate articles given under the different heads. The scheme devised by Professor Lindley is more symmetrical, and in many respects more philosophical, than any other; but the names given to the different groups have not been adopted by many botanical writers. The seven classes of this beautiful arrangement are distinguished by the following characters:—

Class I. Trailourns.—Asexual or flowerless plants, without proper stems or leaves.

Class II. Achogens.—Asexual or flowerless plants, with stems and leaves.

Class III. RHIZOGENS.—Sexual or flowering plants, with acotyledonous embryos and fractification springing from a teallus.

Class IV. Endogens. — Monocotyledonous flowering plants, with endogenous stems, parallel venation, and ternary symmetry.

Class V. DICTYGENS. — Monocotyledonous plants,

Class V. Dictrogens. — Monocotyledonous plants with reticulated yeartion.

Class VI. GYMNOGENS. - Polycocyledonous exogens, with naked seeds.

Class VII. Exogens.—Dicotyledonous plants, with seeds in a seed-vessel. These are arranged in four sub-classes.

Under the above heads Lindley places all the natural orders, which he arranges in groups termed Alliances. A brief notice of the progress of systematic botany may conclude this attempt to elucidate its leading principles. One of the earliest methodical arrangements was that of Casaloinus, a Romon physician attached to the court of Pope Sixtus V. This was entirely artificial; and the same may be affirmed of the several systems of Gesner, Morison, Rivinus, and Tournstort. That propounded by Tournefort was for a long time adopted by the French school, but was ultimately displaced by the attractive scheme of Linnaus, who must be looked upon as the great promulgator of the artificial method of classification. The first attempt at arranging plants according to their natural affinities was made by our great countryman John Ray, in the year 1682. His scheme was necessarily very imperfect, for the number of plants then known was comparatively small; still it was in its leading features correct, and has really formed the foundation of every later system. It was long neglected, and did not receive the attention it deserved until Jussien entered the field, and developed Ray's views of the natural affinities in the vegetable kingdom. Jussieu's method was first made known in the year 17st, just elecen years after the death of Linomia. Since that time, the natural method has been advanced by the labours of De Candolie, Brown, Endlicher,

Lindley, and many others.

4. Geographical Botany treats of the manner in which plants are affected by climate and station, and endeavours to determine the conditions under which parti-

326

## Botany-Bay Kino

cular families or species of plants are confined to certain zones of latitude and altitude. It is a study of great zones of latitude and altitude: It is a study of great-interest, and one which cannot be successfully proce-cuted without an intimate acquaintance with most of the sciences. Of course, so long as there are vast tracts of continents unexplored by botanical travellers, the knowledge upon which this depayment is founded

must be imperfect. (See DISTRIBUTION OF PLANTS.)

5. Fossil Botany investigates the nature of the plants found in a fossil state in the various geological formations. It is therefore at once a branch of botany and

of geology. (See Palmontology.)

The practical bearings of botany are most important. and are sometimes treated separately in manuals of the science, under the head of Economic Botany. All the principal plants affording food, timber, medicine, tibres, dre-stuffs, and other useful products, are noticed in this work under the names of the genera which include them. Many arts and sciences closely connected with botany are explained in separate articles. (See Materia Mindoa, Agrenia Mindoa, Agrenia Mindoa, Agrenia Mindoa, Agrenia Mindoa, Gardenino, Physical Grography.)—Ref. Lindley's Vegetable Kingdon and School Butany; Balfour's Manual of Bolany, Class-book of Bolany, and Bolanis's Companion; Bentley's Manual of Bolany; Babington's Manual of British Bolany; Catlow's Popular Field Bolany.

BOTANY BAY KINO. (See EUCALYPTUS.)

BOTE, bote, is an old Saxon word signifying belp, succour, aid, advantage, recompense, satisfaction, or amends; and is equivalent to eslover, which is derived from the Fr. estaffer, to furnish. It is an allowance of wood for fuel, repairs, and the like, and which every tenant for life, unless restrained by covenant or agreement, may, of common right, take upon the land for his reasonable service, without being impeachable for committing waste. The word is generally conjoined with another to express its nature; as bridge-bate. which is an allowance for making or repairing a bridge; fire-bote, or house-bote, for fuel; plough-bote and cart-bote, for making and repairing implements of hus-bandry; hay-bote, or hedge-bote, for repairing hedges and fences. &c. The term bote and its compounds, and fences, &c. however, though technically proper, have in modern times somewhat fallen out of use.

Bor-FLy, both-fit (Conida).—Although most of these insects are incapable of taking nourishment when in their perfect state, from the obsolete nature of their mouths, they are nevertheless to be regarded as among the greatest pests that afflict catile. During their larva state they are all parasitic upon the various berbivorous animals, some of them harbouring in the skin, and there in the internal cavities of their bodies. In horses these posts are called bots; in sheep, maggots; and in oxen, wornibe. Of the internal parasites, some live in the frontal sinuses of sheep and deer, the parent laying her eggs in the nostrils of the animal, whence the larva creeps up to its destmed abode; whilst others (the bots) make their way to the very core of the animal's intestines. The eggs of these latter are laid upon the skin of the horse in such positions as are easily reached with his tongue. This selection of situupon the sam of the norse in some positions as are easily reached with his tongue. This selection of stuation, however, is not invariable, nor, according to Newman, need it be, to insure the bot's purpose. He says, "All naturalists must have observed how commonly the eggs of the bot are deposited on that part of a horse's shoulders which he can never reach with his mouth; and thus, to a casual observer, it would seem that they must perish, and full in the object for which their parent designed them. Now there is a provision of nature which exactly counteracts this difficulty. When horses are together in a pasture, and one of them feels an irritation on any part of the neck or shoulder which he cannot reach with his mouth, he will arbble another horse on the corresponding part of his neck or shoulder, and the horse so nibbled will immediately perform the and the horse so nibiled will immediately perform the kind office required of him, and begin nibbling away at the part indicated." After the eggs have remained among the hair of the horse's hide four or five days, they arrive so near maturity that the least additional heat is sufficient to hatch them. This additional heat is supplied by the application of the friendly horse's lips and tongue; the larve are liberated, and, adhering roudly to the moist surface of the horse's mouth, are conveyed straight to his intestines. It is satisfactory

# Botrytis

to learn that opinion is at least divided as to whether the bot-fly in the horse's stomach is hartful. The horse has an instinctive horror of this insect, and, a soon as it flies near him, he gallops round the field soon as it mes near nim, he gallops round the field or inclosure until he is in a profuse perspiration, and then comes to a sudden stop, in a state of tramer. The fly makes a most delicate poise on the wing, and then suddenly darts at the horse and deposits an egg. This is repeated until several hundreds are affixed to the heirs, generally of the leg. When the larves become perfect, they pass from the body of the animal with the dung, in which they remain until they are matared into a fly. They frequently attach themselves, by hook-like process, near the anus of horned cattle, and drop with the dung. In the summer months oxen frequently stand in a pond or pool for a considerable time, their instinct leading them to this course in order that they may effectually get rid of their future enemy.

BOTHER, both'-e (Gaelic bothag, a cot), is a name given in the Highlands of Scotland to a hut, or the meanest sort of cottage; but latterly the name has come to be applied to the houses in which the unmarried farm-labourers are lodged, in different parts of Scot-These last are usually of the most wretched tion. Frequently a number of young men are description. thus crowded together in a single apartment, where they have to eat, sleep, dress, and prepare their own meals. They have thus without any control, and great laxity of morals is the consequence. In some places there are also bothies for unmarried female farmservants, which are still more reprehensible. During the last few years, popular attention in Scotland has been much directed to the evils of the bothic system, both through the platform and the press, and it has been almost universally condemned. No one has done more to overthrow this system than the Rev. Dr. Begg. of Edinburgh.

of Editinurgh.

BOTHRODENDRON, both!-ro-den!-dron (Gr. bothros, pit. dendron, tree), in Geol., a gen. of iossil stems, with dotted surfaces, occurring in the coal-measures. and distinguished from Sigillaria and Stigmaria by two opposite rows of deep aval pits, which appear to be the sears left by large cones or seed-bracts.

BOTONOMENCY, of to-on-omes seed-oracts.
BOTONOMENCY, of to-on-omes seed-oracts, a plant, manteio, divination), a method of inquiry into the future by means of plants. The plan, sometimes adopted by young ladies, of picking off the petals of flower, one by one, to see whether a certain event will or will not happen, is one way of practising botono-mancy. This species of divination was anciently prac-tised by writing a number of letters or words upon leaves, and then exposing them to the wind, when the answer was attempted to be made out of those that Sometimes the noise or crackling of leaves remained. when crushed between the hands or cast into the fire was the mode resorted to.

was the mode resorted to.

Bothy clearing the description of the division of grapes), in Bot., a gen. of ferns of the division ophinglosses. The only British species is B. lanaria, commonly called Moonwort, a little fern common on mountain pastures. B. virginicum is found in many parts of America, Asia, and Africa; but in Europe it is strangely contined to Norway. Its fronds, which are large and succulent, are boiled and eaten in the Himsland Naw Zouland cond. Conference of the Principles of the condition of the parts of the condition of the co

the Himalaya, New Zealand, and a few other parts.

Borryothal, bot'-ri-oi-dal (Gr. botrus, a bunch of grapes), in Min., a term applied to masses occurring in a concretionary form resembling bunches of grapes. Certain limestones and hamatites are found in this

BOTHYOLITE, hot'-ri-o-lite (Gr. botrus, a bunch of grapes, eidos, like), datholite or boro-silicate of lime, occurring in a botryoidal form at Arendahl, in Norway. It is also found near Lake Superior in such large quantities, that it has been used as a flux for

#### Bottle-Pish

name of suscersiss, is produced by one or more; a disease to which turnips are particularly hable is connected with the growth of the species B. parasities; and the much-dreaded potato disease is confidently sacribed by many observers to B. infeatans.

Horrus-Fiss (Sacopharyux ampullaceus), a very singular fish, belonging to the gen. Sacopharynx. Only two specimens of the genus have been taken, and, with the exception of size, they realize many of the fabulous accounts of the sea-server. One was exacult in the

accounts of the sea-serpent. One was caught in the chtrance to Davis' Straits, and measured four feet and half, and the other between Iceland and Labrador, it was fix feet long. The most singular fact connected with the bottle-fish is, that its oody is capable of being inflated like a leathern bot-

tle, and it has along slender tail like a whiplash. It has a pointed mout, and its

mished with long sharp teeth. Under the smail pec-torals the three branchials can be seen through the irregularly-shaped gill-openings; and the extensibility of the jaws is greater than that of the serpent tribe. It has a slightly granular, but soft, loose, and slimy skin, and is very voracious; one of the examples referred to was discovered to have swallowed a fish longer than its own body, and the other a sea-perch thicker than itself.

BOTTLE PAPERS, bot'-tel, is a term applied to those papers that are inclosed in bottles and cast into the es. Sometimes intelligence of the sinking or destruction of a vessel is communicated in this way; but they are commonly made use of in showing the drifts and currents of the ocean. In such cases the ship a name, the latitude, longitude, date, &c., are written down on a slip of paper, which is then put into a bottle, properly secured, and cast into the sea. These papers are frequently drifted away into very distant localities, and, when picked up, often supply useful information to the hydrographer.—Ref. Nautical Magazine for Sept., 1837.

BOTTLES (Fr. bouteilles). — The manufacture of bottles is one of considerable importance. This may be seen from the fact that France uses annually over 60,000,000 of bottles for wine alone. The bottle manufacture of Great Britain is very After supplying our own wants, which flourishing. are enormous, we export common bottles annually to the amount of over £300,000. Bottles destined to contain acid, or effervescing wines, are made with particular care, a machine having been invented for testing their strength. Before this the loss of champague bottles by bursting was nearly 30 per cent. For soid wines the glass should contain a slight excess of silica : otherwise, the lime or alkali left uncombined is acted upon, and the bottle corroded. For more information on this subject see GLASS MANUFACTURE.

Borrom, bot'-tom, a term frequently used it com-mercial language to denote a ship, as when we speak of goods imported in foreign bottoms, or in British bottoms. The word is derived from the Dutch bodem, which originally signified the bottom or keel of a ship, but came afterwards to be used also for the whole resel. The term is also used in both senses in Euglish.

Borrow Beds, in Geol., the name sometimes given to some partially or doubtfully fossiblerous strata which immediately underlie the Silurian system in Wales.

BOTTOMEY, bot tom-re, in Law and Com., is in the usture of a mortgage of a ship, and is said by Blackstone to have originally arisen from permitting the master of a ship, in a foreign country, to hypothecate the thip, in order to raise the money to refit.—(2 Bl. Com. 457.) It arises when the owner takes up money to conside him to carry on his voyage, and pledges the keel or bottom of the ship (partem protanto) as a security for the repayment; in which case it is understood that, if the ship be lost, the lender loses the whole of his money; but if it returns in safety, then he shall receive back his principal, and also the premise or

## Boulders

interest agreed upon, however it may exceed the legal rate of interest, it being considered in the nature of an rate of interest, it being considered in the nature of an insurance, and not usery. And this is allowed to be a valid contract in all trading nations. In this case, the ship and tackle, if brought home, are answerable (as well as the person of the borrower) for the money lent. But if the loan is not upon the vessel, but upon the goods and merchandise, which must necessarily be sold or exchanged in the course of the voyage, then only the borrower, personally, is bound to answer the con-tract, who, therefore, in this case, is said to take up money at respondentia. These terms are also applied to contracts for the repayment of money borrowed, not on the ship and goods only, but on the mere hazard of the voyage itself; when a man lends a merchant £1,000, to be employed in a beneficial trade, with condition to be repaid with extraordinary interest, in case such a voyage be safely performed; which kind of agreement is sometimes called faxus nautious, and sometimes usura marilima. But as this gave an opening for usurious and gaming contracts, especially upon long voyages, it was enacted by the statute 19 Geo. II. c. 37. that all moneys lent on bottomry or respondentia, on vessels bound to or from the East Indies, shall be expressly lent only upon the ship, or upon the merchandise; that the lender shall have the benefit of salvago; and that if the borrower have not an interest in the ship, or in the effects on board, equal to the value of the sum borrowed, he shall be responsible to the lender for so much of the principal as bath not been laid out, with legal interest and all other charges, though the ship and merchandise be totally lost. The observation and merchandise be totally lost. The observation above as to the rate of interest applies to the laws of each particular country fixing the legal rate to be taken, the usury laws in England baving been re-pealed.

BOTTONNY, bot'-ton-ne (Gr. botane, a plant), in Her., the name given to a cross the ends of which terminate in three semicircular projections, giving them an appearance resembling the trefod in form.

BOUDDIR, boo'-dwaw (Fr.), a lady's small private apartment, in which she receives only her most intimate friends. Boudoirs became very fashionable in France during the reign of Louis XIV., and were frequently adorned in the most luxurious and fantastic manner.

 BOUGET, boo'-zhai (Fr. bouget), in Her., a charge of peculiar form, representing an ancient vessel used for the purpose of carrying water.

BOUGHT AND SOLD NOTES, in commercial trans-actions, are notes of sale signed by a broker employed to sell goods, and by which the bargain is completed. They contain the conditions of the bargain, and are afterwards delivered to the principals for implement.

Bougis, bon-zhe' (Fr.), a surgical instrument used for opening obstructed passages of the body; as the urethra, rectum, resophagus, &c. It is long and slender in form, solid or hollow, stiff or flexible, according to its particular use, usually varying from 4th to 14th of an inch in diameter. It is made of various substances, as German silver or pewter, gum-elastic, catgut, &c. One kind is also made by dipping a fine cord or thread of flax or silk in melted wax until it has acquired a sufficient thickness, when it is rolled smooth and firm on a marble slab. Bougies require to be employed with skill and caution, as there is always a considerable degree of danger attending their use. If used at all by inexperienced hands, the utmost caution should be observed, as much injury may arise from any hasty or violent efforts to remove the resistance that may present itself; it is rather to be overcome gradually and by repeated attempts, so as not to excite much pain or irritation.

BOULDER CLAY. (See DRIFT.) BOULDERS, bule'-ders (Sux.), in Gool., any rounded or waterworn blocks of stone too large to be included under the heads of "pebbles" and "gravel." The term erratic boulders is generally applied to the detached masses of rock which are foundlying upon the surface, and which have been washed out of the clays of the Glacial epoch, or brought separately from their original sites by icebergs. They are often found resting on hill-tops, which during the Glacial period were banks and shallows in the sea, and so arrested the laden icebergs in their course. The largest boulder known in the British islands is near the head of the Devil's Glenis

#### Boulevard

custy Wicklow. It is 27 feet long by 18 wide, and 15 county Wicklow. It is 27 feet long by 18 wide, and 15 high. It is of granite, resting on Cambrian grits and slates, six or eight miles from the nearest granite is sta, with a wide shallow saley between the hill on which it now stands and the granite district. Very large erratic blocks of Scandinavian rocks are scattered over the plains of Denmark, Prussis, and northern Germany. The monolithic pedestal of the statue of

ERRATIC BOULDERS.

Peter the Great at St. Petersburg was hewn out of a boulder weighing 1,500 tons, that lay on a plain not far from the city. (See DRIFT, GLACIER, PLRISTOCRNE.)

ROULEVARD, or BOULEVART, book-road (Ger. bolk-werk; Eng. bulwork), is a French term denoting the outer fortifications or ramparts of a town. Many of these have now been levelled, the ditches filled up, and the space laid out in public gardens, parks, and pro-menades firely shaded with trees, but still retaining their old name. The boulevards of Paris are the most magnificent of their kind.

Buguincent of their kind.
Boulings, how'd homs (Gr. bon, great, and limos, hunger), is a word used in medicine to denote a canine or vorncious appetite. The terms canina or bound fames (Lat. canis, a dog, or bos, an ox, and fames, hundranes) ger), are sometimes used in the same sense.

BOUNDARIES OF CITIES AND BOROUGHS, boun'-dores (Nor. boune, a limit), in England, are declared by the Municipal Corporations Act, 5 & 6 Will. IV. by the Municipal Corporations Act, 5 & 6 Will. IV.
c. 76, to be the same as those settled and described
in 2 & 3 Will. IV. c. 64, being entitled "An Act
to settle and describe the divisions of counties and
the limits of cities and boroughs in England and
Walca, so far as respects the election of members
to serve in parliament." This act was, in some points,
subsequently anended by 6 & 7 Will. IV. c. 103. Act 7 Geo. IV. c. 64. declares that when any felony or misdemeanour shall be committed on the boundaries of two or more counties, or within 500 yards of such brimilaries, or shall be begun in one county and complette in another, such may be dealt with and tried in

BOUNDARIES OF PARISHES depended upon ancient usage, and were not limited by not of parliament until the passing of the statutes after mentioned; and where these have not been applied, the usage still exists; and in many places great care is taken to perpetuate the memory of the boundaries by perambulations from time to time, which are called beating the bounds. In some places parishes seem to interfere, when some place in the middle of one purish belongs to another that is distant; but this has generally happened by a unity of possession, when the lord of the manor was at the charge to creet a new church, and make a dis-tinct parish of his own demesnes, some of which lay in the compassor another parish. Some lands were never

# Bounty

at all united to any parish, and remain to this extra-parochial. The oustom of perambulating pariduring Rogation week (the next but one before W Sunday) was first introduced, with other Romi monies, by Claudius Mumertus, a French bid Vienne, in the year 550, whose precedent was social vienne, in the year 550, whose precedent was social afterwards repeated by Sidonius, bishop of Clermont, and at length established by the council of Orleons. The regulation of Queen Elizabeth relating to the East first regulation of Queen Litzaueth remains to the coa-glish ambarvatia, or processions, is as follows:—"The people shall once a year, at the time accustomed, with the curate and substantial men of the parish, walk about the parishes, as they were accustomed with willow wands), and at their return to church, make their common prayers; provided that the said ourste, in the said common perambulations, as heretofore in the days of Rogations, at certain convenient places, shall admonish the people to give thanks to God, in the beholding of God's benefits, for the increase and abundance of his fruits upon the face of the earth, with the saying of the hundred and fourth Psalm, Benedic anima mea, &c., at which time also the same minister shall inculcate this and such-like sentences, Cursed be he which translateth the bounds and doles of his neigh-bour,' or such other order of prayer as shall be hereafter appointed." Parishioners being legally entitled to make these perambulations, it has been held that they may justify going on a man's land, or into his house, if on the necessary track. In the case of Taylor v. Devey, 7 Ad. & Ellis, 412, Lord Denman, in giving the judgment of the court, said,—"The right to perambulate parochial boundaries, to enter private proamounte percental boundaries, to enter private pro-perty for that purpose, and to remove obstructions that might prevent this from being done, cannot be disputed. It prevails as a notorious custom in all parts of England, is recorded by all our text-writers, and has been confirmed by high judicial sanction." In the city of London the custom is, in most parishes, exercised yearly on Ascension-day, or Holy Thursday; and the inns of court and other extra-parochial places bar out, by shutting their gates. By the statute for commutation of tithes, 2 & 3 Vict. c. 62, the tithe commissioners are authorized to adjust the ancient boundaries between parishes and townships, or to define a new boundary, as they shall think fit; which adjustment is declared to be binding for all purposes whatever. And by 8 & 9 Vict. c. 118, s. 39, similar powers are intrusted, under certain circumstances, to the inclosure commissioners for England and Wales. The boundaries of the town-ship and parish of Wolverhampton were, in many parts, marked out by what are called Gospel trees, from the custom of having the Gospel read under or near them by the clergyman attending the perochial perambulations.

BOUNDARY SURVEY OF IBELIND. (See SURVEY, ORDNANCE.)

BOUNDING CHARTER, OF INFEPTMENT, boun'-ding, in Scotch Law, is a charter or infettment which describes the lands by their boundaries or marches. Such a description confers right to all within the bounds, and on the other hand, excludes whatever lies beyond. If described as bounded by certain walls, these will not be held as conveyed, unless this be expressly stated; and where it is intended that the wall should be mutual, this must be expressed.

BOUNTY (Fr. bonte), in Pol. Ec., is a premium paid by government to the producers, exporters, or importers of certain commodities, with the view of encouraging the prosecution of these branches of industry. system arose out of the notion that there were certain kinds of industry which it was specially the interest of the government to encourage or to prevent from falling into decay. Bounties were at one time very numerous in this country; but since the appearance of Adam Smith's "Wealth of Nations," wherein their impolicy is clearly pointed out, the system has fallen into disrepute, and is now almost universally condemned.
According to that author, a trade is only in a natural According to that author, a trade is only in a natural condition when its produce is sold for a price which replaces the whole capital expended in production, and leaves something over in the shape of profit. When this is not the case, and when the goods can only be sold at a loss, the manufacturer will cease to produce an unprofitable article, unless the government comes forward with a bounty to establish an equilibrium be-

## Bounty

tween the cost of production and the market price.
"The bounty," says Adam Smith, "is given in order to make up this loss, and to encourage a man to continue, or, perhaps, to begin a trade of which the ex-pense is supposed to be greater than the returns; of which, every operation eats up a part of the capital employed in it, and which is of such a nature, that if all other trades resembled it, there would soon be no capital left in the country. . . The effect of bounties, therefore, can only be to force the trade of a country into a channel much less advantageous than that in which it would naturally run of its own accord." system of bounties entirely ceased in this country in 1830, unless one may class under this head the large parliamentary grants made to certain steamboat com-panies to run boats for the carriage of the mails, analogous to, and closely connected with bounties, is the system of drawback of duties allowed upon the exportation of certain articles, which still continues to ene extent. (See Drawback.)
BOUNTY, or QUEEN'S BOUNTY, is a sum of money

given by government to persons enlisting in the army or navy, in order to induce men to enter these services. The amount of bounty naturally varies with the demand for men, being sometimes as low as £2 or £3; while at other times, as during the war against Napoleon, it has been as high as £20 or upwards. Formerly, a great part of the bounty was usually kept back, under the plea of being payment for certain articles furnished; but recently an outcry was made against this practice, and a sw the recruit receives the whole amount of the

bounty in cash.

BOUNTY, QUEEN ANNE'S.—The profits of the first-fruits and tenths which were anciently given to the pope were, by Henry VIII., appropriated to the crown. Queen Anne restored this source of revenue to the Church, and caused a perpetual fund to be es-tablished, the revenue of which, after payment of certain charges and pensions, was vested in certain trustees for the augmentation of poor livings under £50 per annum. This fund has been further regulated by subsequent statutes. The trustees are certain dignitaries of the church, and other official persons for the time being, and are incorporated under the name of " the Governors of the Bounty of Queen Anne, for the augmentation of the maintenance of the poor clergy. They have authority to make rules for the distribution of the fund, which are to be approved by the king under his sign manual. The sum received by the governors of this bounty for the year ending 1853 was £233,070, and they expended £243,136.

Bouquer of Wink, boo'-kai (Fr.), the odorous principle or perfume in all wines, partly derived from the grape and partly from fermentation. It has some of the characters of an essential oil, and in some wines of the characters of an essential oil, and in some wines is present in small quantities, and is very evanescent; while in others it is abundant and persistent. According to Pelouze and Liebig, the bouquet of wines, which they consider to be a substance formed during fermentation, is a true ether, namely, a combination of oxide of ethyle with conanthic acid.

Bourson Tra. (See Angrecum.)

Bourselsie, boorzh-waw-ze (Fr. bourg, a town), is a French term, literally signifying the inhabitants of a town, and is employed to denote a class of society in

town, and is employed to denote a class of society in France who inhabit the towns, and are intermediate between the nobility and the lowest class of the people, including merchants and manufacturers down to master tradesmen. Under the ancient monsrchy it com-prised all those who were called upon to partake in the duties or participate in the expenses of the town in which they were domiciled. The bourgeoisie of the large towns have often played an important part in the history of the country. They are not to be confounded with the citoyess, a general term applied to all who are members or citizens of the state.

BOURIGEONISTS, boo'-reen-yo-nists, in Eccl. Hist., a was born at Lisle, in France, 1610. She pretended to was born at Liste, in France, 1816. She pretended to particular inspirations, and set herself up as a religious preferred by the English howmen. It was considerably with very singular notions. She found a number of less cambrous than the cross-bow, and more than followers, one of the principal of whom was Peter Poiret, an able and less ned man, who, in his "Divine Resonance," attempted to reduce the substance of Bosonance, and so the substance of Bosonance, and substance of Bosonan

#### Bow

rignon's fancies to a regular system. One Dr. Garden of Aberdeen, who wrote an apology in their favour, was condemned and deposed by the General Assembly in 1701. The works of Bourignon were published by Poiret at Amsterdam, 1676-84 (2nd edition 1717), and

cocupy 25 volumes.

Bournonire, boor no nite, a mineral occurring at Budellion, in Cornwall, in steel-grey tabular crystals, or massive granular aggregations. It is a mixed aulphide of antimony, copper, and lead. It is often found in masses resembling a cogged wheel, and is thence called

wheel-ore. It is also known as Endellionite.

BOURNOUSE, boor-noose, a large woollen maptle with a hood, which is thrown over the head in wet weather. It is worn by the inhabitants of Algeria and other parts of Northern Africa. The bournouse is put over the rest of the attice and is addressed as a put over the rest of the attire, and is coloured as as to suit the fancy of the wearer. White, however, is the principal colour. The name is Arabic, but amongst the Spaniards this garment has long been known under the name of albornoz. Since the conquest of Algeria by France, the term has been applied to a lady's cloak with a hood attached behind, which somewhat resembles the Arabian bournouse.

BOURSE. (See EXCHANGE.)

BOUSTROPHEDON, boo-strof-e'-don (Gr. bous, an ox, and strepho, I turn), a term used to denote that mode and excepts, I turn), a term used to denote riar mode of writing which was practised by the Greeks in the earlier period of their history. Instead of each line proceeding from left to right, they proceeded from left to right and right to left alternately, so that each line commenced at the side at which the previous one terminated, like oven in ploughing, and hence the name.

Bousy, boo'se (Ang. Sax.), is applied to one who is intoxicated or who drinks lavishly. It is said to be derived from buyse, the Dutch name of a large drink-

ing-cup with two handles.

With a long legend of romantic things Which in his cups the bousy poot sings

Druden.

Bours Rimes, boo-re'-mai (Fr., rhymed endings), a social amusement, which consists in making lines to suit certain rhythmical terminations which are given. It is said to have originated with one Dulot, a French mediocre poet of the 17th century, and was at one time extremely popular in that country. In fixing the bouts, it is usual to choose such as seem the remotest and have the least connection.

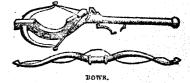

Bovza, boo'-za, a kind of beer made from the grains of an Abyssinian corn-plant called Toff. (See Pos.)

BOVIDE, bo'-vi-de (Lat. bos, boxis, an ox), the hollowhorned ruminating animals belonging to the class Mammalia, order Reminantia. The species belonging to this family are hoofed, their stomachs being adapted for chewing the end. Their frontal bones are usually provided with hollow borns. In this family are included, Borina, the oxen; Giraffina, the giraffes; Cervina, the deer; Moschina, the musk-deer; and Camstina, the camels.

Bow, bon (Aug.-Sax.), in Mar., is that portion of a ship's side which forms an arch towards the stem. tre are two kinds of bows; viz., lean, or narrow, I luff. or broad bows. The former of these is best and luff, or broad bows.

calculated for swift sailing.

Bow, one of the oldest of weapons, in the use of which the English, during the Middle Ages, were extraordinarily expect. In the annexed illustration are shown the long-bow and the arbulest, or cross-

Bow

to is. id., a sheaf of arrows costing from is. to is. 2d. Some long-bows were made of the shape shown in the cut,—a double arch connected by a straight piece. (See

ARBALEST, ARCHERT.)

Bow, in Mus., a stick of hard elastic wood, along which are stretched horse-hairs, the tension of which is regulated by a screw. It is used for playing upon instruments of the violin kind, and varies in vize, the double-bass and violoncello bow being much stiffer and stronger than that of the violin.

BOWDICHIA, ho-dik'-i-d, in Bot., a gen. of plants belonging to the nat. ord. Leguminosæ, sub-ord. Papidionaces. The only species requiring notice is B. virgilioides, the bark of which, with that of one or more species of Byrsonima, forms the American alcornoco

bark of commerce. (See BYESONIMA.)

BOWIE-KNIFE, bo'-e, the name of an American sharp pointed weapon, bearing a close resemblance to the French contenu de chasse, or English butchers'-knife. A story is told of its having been introduced into America by a certain Col. Jim Bowie, of Texas, who acquired great notoriety by the skilful manner in which he wielded the weapon in his hand-to-hand encounters with Mexicans and others. In the Southern States of America it was commonly carried in a sheath secreted comewhere about the person.

BOWING, OF WORSHIPPING TOWARDS THE EAST, Was the practice of the Church from a very early period. Various reasons have been assigned for this custom; as, the appearing of the star in the east at the birth of Christ; the rising of the sun in the east being emble-matic of the rising of the Sun of Righteousness; the belief that Christ would make his appearance in the east when coming to judge the world. Hence it became customary to place the altar and other sacred symbols at the eastern extremity of the church. The west, on the other hand, was regarded as the place of Satan and darkness; and hence, when they renounced their sins, they looked towards the west, and then turned about to the east to make a covenant with Christ,

Bowing THE HEAD, in the early Christian church, was considered as a posture of worship, and inter-mediate between standing and kneeling. It was observed principally in receiving the hislop's blessing, and in all direct and formal addresses to God for his In the early mercy and favour upon the people. church it was also usual to how the head whenever the name of Jesus occurred in the service, and in the Church of England this is still done in repeating the

Creeds.

BOW-LINE, in Mar., a rope fastened near the middle of the lecch, or perpendicular edge of the square sails, by three or four suindinate parts called bridles. It is only used when the wind is so unfavourable that the sails must all be braced sideways, or close-hauled to

Bowns, boles (Fr. boule), a favourite game in Britain, played upon a smooth, grassy surface, either square, circular, or oblong, used only for the purpose, and called a bowling-green, which is surrounded by a trench about half a foot deep. Bowls are made from a black, green wood, called lignum vitæ (Guaiacum officinale); they are nearly round, and have a diameter of six or oight inches, with a bias to one side. The party playing may consist of two, four, six, or eight, and is gene-The party playrally chosen after tossing up a coin to decide who shall have the first choice. The sides being selected, each player has two bowls, which are marked with numbers, thus distinguishing the players. The sides being s iested, the leader of the game sends off a small white ball from one end of the bowling-green to any distance he pleases. This small white ball is called the jack, and the leader throws his first bowl so as to place it as near the jack as possible. He is then followed by one of the adverse party, the partner of the first following, and so, in rotation, till all the bowls are played. The some is won by the side whose bowls are nearest the jack. The number of points required to make the game is arranged beforeland; 7, 14, 21, or 31, are the numis arranged beforeland; 7, 14, 21, or 31, are the numbers usually fixed. Great disappointment often happens to a player when his bowl, after being placed close to the jack, is removed by a blow from a subsequent player's bowl. This is called a "rub." Hence the old lines to a player's bowl. This is called a "rub." Hence the old lines of the player's bowl is a blow in must expect rubs." Under Ivan, a number of these privileges and immunities. Some are weighted or bissed on one side, in order the method that the lease time, offices were best of the method that the lease time, offices were best of the method that the lease the lines of the country, and stood in somewhat the same relation to the must be a more than the same time of the same relation to the must be a more than the same time of the same relation to the must be a more than the same time, offices were best of the more than the same time, offices were best of the must be a more than the same time, offices were best of the must be a more than the same time, of the must be a more than the same time, of the must be a more than the same time of the must be a more than the same time.

Boyer

that the player may be able to bowl towards the jack in a curved direction. A fore-hand bowl is played with a curve from the fight, and a back-head bowl with a curve from the left. If a bowl goes into the dison without striking the jack, it does not some; but if it strikes the jack and goes into the ditch, it reckons as if it were upon the green. When the jack itself is knocked into the dich, it is replaced upon the green, in the place nearest to where it lay in the dich. The game of bowls was prohibited in England during the reign of Henry VIII. by set of parliament; that law, however, was repealed in 1835. It has always been a favourite matrime in the Reitish isles pastime in the British isles.

Bowls, AMERICAN, is a game of modern invention, cently introduced into England from across the Atlantic. It is played in saloons fitted with alleys of from fifty to sixty-five feet in length, and about four in width. The alley has a "gutter," as it is called, on each side, and is very slightly convex in the centre, regularly bevelled to the sides. At the further extremity of the alley are set up, in the form of a pyramid, ten pins, usually of ash-wood, about a foot in height and 2 lbs. in weight. The spex of the pyramid turned towards the howler, who rolls wooden balls, generally of lignum vites, with the object of knocking down as many of the pins as possible at each roll. The pins, when set up, are called a frame, and at each frame the bowler rolls three balls, when the number of pins down is counted to him, and the frame is set up again for the next bowler. A game ordinarily consists of ten frames, or thirty balls. If the bowler takes all the pins with his first ball, he counts ten; the frame is again set up for his second ball, when, if he again takes all, he counts ten more, and the frame is again set up for his third, when, whatever number he scores with the three balls, count to him as if all had been made off one frame. If he take all the ten pins with his first two halls, he is entitled to a fresh frame for his third or last ball. This is technically called getting. spare, or double spare. The above is the strict game, as played in the bowling-saloous of the Broadway of New York; but in England sometimes it is played somewhat differently.

Powsprit, bo'-sprit, in Mar., a large boom or mast, which projects over the stein at an angle of about 36 degrees, for the purpose of carrying the sail forwa to govern the fore-part of a ship, and counteract the force of the after-sails, or those extended behind. bowsprit is otherwise of great use, as it is the principal support of the fore-mast, by contining the stays (or ropes stretching from the top of the mast to the bowsprit), by which it is secured and enabled to carry sail.

Bow-Window. (See Bay-Window.) Box, in Bot. (See Buxes.)

Box-Days, in the legal phraseology of Scotland, are wo days appointed by the judges of the Court of Se sion in each of the spring and autumn vacations, and one day in the Christmas recess, on which papers ordered by the court, or by the lords-ordinary, towards the close of the previous session, are usually appointed to be lodged.

BOX-HAULING, box-hawl-ing, in Mar., a particular method of veering a ship when the swell of the sea

renders tacking impracticable.

Boxing. (See Pugitism.)

BOXING-DAY, in England, is the day after Christmas, and is so called from the custom of giving Christmas boxes, or presents to servants and others, on that day.

BOXING THE COMPASS is a see phrase denoting the epetition of the several points of the mariner's compass

in their proper order.

BOYAE, BOYAE, or BOYAED, bo-yar' (Selavonic, a free possessor of land), was a general name applied to the class of noblity in Russia. They were originally distinguished warriors in the armies of the early conquerors of the country, and hence they received large grants of territory, and came to acquire great power. They were next in order to the railing princes of the

#### Boy-Bishop

Brachiopeda

stowed upon many of them about court, which, by degrees, withdrew them from their allegiance to the princes, and led to the overthrow of the latter. Peter the Great finally abolished the order of the boyars, by stripping them of their remaining privileges, and giving them a place among the Russian nobility. In Moldavia and Waikechia, boyars still erist, and have a soat and voice in the council of the prince.

Boy-Branor, bot bish op.—Anciently, on St. Nicholas's day, December 6, it was the custom for the choirboys in the cathedral churches to choose one of their number to maintain the state and authority of a bishop.

number to maintain the state and authority of a bishop. For this purpose he was habited in rich episcopal robes, had a mitre on his head and a crosier in his hand, and his fellows for the time being assumed the character and dress of priests, yielding him canonical obedience. They took possession of the church, and performed all the ecclesiastical ceremonies and offices except mass. The office and authority of the boy-bishop proclamation of Henry VIII., dated July 22, 1542, the show of the boy-bishop was abrogated; but, in the reign of Mary, it was revived, with other Romish ceremonials, to cease in the reign of Elizabeth.—Ref. Read's 2 purplus defaulties. Brand's Popular Antiquities, by Ellis.
Borsav, bicoi'-yo (fr. boyau, bowels).—The name

BOYSAV, bwoi'-yo (fr. boyau, bowels).—The name given in Mil. to any covered line of approach made owards the defensive works, during the siege of any place, by the attacking party. Boyeaux are termed parallel or zigzag, according to their direction with reference to the front of the work against which the

attack is directed.

BOXLE'S FUMING LIQUOR, boils, so called from having been invented by Robert Boyle, one of the fathers of chemistry in England. It is obtained by distilling one part of sulphur, two parts of chloride of aramonium, and two parts of lime. It is a mixture of several sulphides of ammonium and water. It is a

yellowish out liquid, with an intensely fethi odour. It is a very rarely used in medicine under the name of Liquor fumans Boylii.

BOYLE'S LECTURES, a course of eight annual lectures founded by the Hon. Robert Boylein a codicil annual to his will dated 1801. For the support of this lecture. to his will, dated 1691. For the support of this lecture he assigned the rent of his house in Crooked Lane to some learned divine within the bills of mortality, to be elected for a term not exceeding three years. The fund proving precarious, the salary was ill paid, and to remedy this, Archbishop Tennison procured a yearly stipend of £50 for ever, charged on a farm in the parish of Brill, Buckinghamshire, to be substituted. The design of the lectures, as expressed by the founder, is design of the lectures, as expressed by the connect, to prove the truth of the Christian religion against infidels, without descending to any controversies that may exist among Christians themselves. He is further to assist and encourage all companies in any undertaking for propagating the Christian religion. To this taking for propagating the Christian religion. To this foundation we are indebted for many elaborate defences of natural and revealed religion. A collection of these sermons, from 1692 to 1732, was published under the title of "A Defence of Natural and Revealed Religion, 3 vols. folio; and in 1737 an abridgment of many of the lectures was published by Gilbert Burnet, vicer of Coggeshall, in 4 vols. 8vo. Since number of the series have been published. Since that time a

BRIBARCIONES, OF BRABAROONS, brd'-ban-sawings, in the Middle Ages, were a kind of irregular soldiery of the Netherlands, who were infamous for rapine, being little better than commissioned banditt, and who hired themselves to fight for whoever would pay them best. Sometimes they were in the service of one prime or haron, and sometimes of another; but they often acted in an independent manner, setting govern often acted in an independent mainer, setting governments at defisione, infecting highways, pillaging the open country, and disturbing the public peace. They formed a kind of society or government among themselves, disregarding every other authority. The greatest monarchs were not ashumed, on occasion, to have recourse to their assistance; and as their manner.

whose fidelity he could repose any confidence. (See Hume's History of England, vol. i. chap. 9.) The name is variously written, but all the historians of the time derive it from the country of Brabant, which was the chief nursery of these troops.

BRABAROONNE, bra'-ban-son, the national song of the Belgians, which was sung during the rerolution of 1830. Its author was a young Fronch actor of the name of Jenneval, and it was act to music by Campenhout. Each verse ends with the refrain-

> " La mitraille a brisé l'orange Sur l'arbre de la liberté,

BRACE, or BRACE, brük'-se, the name given to trowsers, pantaloons, and other articles of armour and dress worn by the nations encircling the ancient Roman and Greek populations. The Latin word bruces corresponds with the Scotch word breeks, and the English word breeks. Trowsers, or bracem, were worn by

word breeches. the Medes and Persians, the Parthiaus, tite Phrygians, the Sacæ, the Sar-mate, the Dacians and Octa, Teutones, the the Belgæ, the Britons, and the Gauls. The Persian and Cossack trowsers of the preslightly very from those which were worn in ancient times. In ancient monuments the nations mentioned above are all

represented in trowsers, in order to distinguish them from Greeks and Romans. The illustration represents two Sarmatians, and is taken from Trajan's Column. Bracce were principally made of woollen materials, but they were sometimes made of silk and leather. They were sometimes striped, and cruamented with a woof of various colours. The aucient Greeks never wore them, but they were generally adopted by the Romans in the 2nd century of the Christian cra.

Brace, braises (Fr. embrases, to embrace, bind together), in Arch., a piece of timber placed in a slanting direction, and fastened at either end to the principal timbers of the roof of a house to add to their strength and stability. The brace was formerly used in typography to connect three lines of poetry forming

a triplet. Brace ( ), in Mus., is a double curved line, which is placed vertically at the beginning of the stave of any composition, and which is used to bind the harmonizing parts together, in order to guide the eye with greater facility from one set of staves to another. When more than two staves are joined together, either for part-singing or playing in concert, it is usual to draw a smaller brace within the large one, in order to distinguish each part. This union of braces is called a score,

BRACED .- In Her., when three chevronels are drawn

interlacing each other, they are said to be braced.

Brackler, braiss'-let (Lat. bracklum, an arm), an ornament generally worn encircling the wrist, but sometimes on the arm above the elbow. (See ABMLET.)

BRACHINUS. (See BOMBARDIER BEETLE.)

BRACHIOFODA, bra-ki-op'-o-dd (Gr. brackion, an arm, pous, a foot).—A term applied to certain molinecous animals having bivalve shells. They derive their name from the remarkable organs by which they procure their food. From the sides of the mouth project two have recourse to their assistance; and as their manner animals having broker shells. They derive their name of life gave them experience, hardshood, and courage from the remarkable organs by which they procure from the remarkable organs by which they procure from the remarkable organs of which they procure from the aides of the mouth project two bines. Henry II. of England enlisted numerous when not used for seigning the prey. These organs are not only used for obtaining food, but also in maintains affairs rendered even such banditti the only forces on

#### Preching

Brachium

The Brachiopola, or Pallio-branchiate, differ from the great majority of recent mollusks with hivalve shells, both internally and externally. The species now existing are very widely diffused, and are all marine; one of them, the Crania personata, has been brought up from a depth of more than 400 yards.

Brachium, brackishum (Gr. brachion, the arm), in Anat., is the name given to the arm, or that part of the upper extremity which extends from the shoulder to the wrist. The term brachial, hence, forms part of the name of certain portions of the arm, as the brachial muscle, the brachial artery. The brachial muscle, or brachialist internus, is situated on the fore part of the os humeri. It rises fleshy from the middle of the os humeri at each caide of the insertion of the deltoid muscle, covering the inferior and fore part of the bone, and is inserted the inferior and fore part of this bone, and is inserted by a strong short tendon into the coronoid process of the ulna. Its use is to bend the fore-arm. The branchief artery is a continuation of the axillary artery, which takes this name as it passes behind the tendon of the pectoralis major. It runs down the inner side of the arm, along the mner edge of the biceps muscle. of the arm, along the more edge of the breeps musers, behind the venn basilien, giving off several small branches in its course. Below the bend of the arm it divides into two branches,—the cubilalis and radialis.

BRACHESTOCHEORS, brain-kib-lo-krone (Gr. brachus, short; stoick-ton, a line), a term employed to

designate the curve described most rapidly, between two points in its course, by a falling body. The term was first used by John Bernoulli, professor of mathematics at Groningen, in 1696, who first drew the at-tention of philosophers to it. The curve is commonly called "the line or swiftest descent."

BEACKET, brak-et (Lat. brachium, an arm), a term applied to any projection, plain or ornamental, suspended against, or fastened to a wall, for the sup-

BRACKET.

port of a clock, statue, lamp, &c. The pieces of wood that are often used to support shelves are so called. The word bracket should not be taken as synonymous with "correl" (see CANTILEVER, CORBEL). as the latter, aithough serving a similar pur-pose, is invariably built into the wall, and not merely fastened to it. In

Mar., the knees which support the stern galieries of a ship are called brackets, and in gunnery, the expres-sion is used to denote the cheeks of the carriage of a

words or sentences; thus. [ ]. BRACKLESHAM BEDS, brak-el-sham, in Geol., the lower tertiary sands and clays immediately overlying the London clay, so called from being well exposed at Bracklesham Bay, near Chichester. They contain the gigantic occidinm (which see), volutes, cowries, bones They contain the or names, crocodiles, and sea-scrpents.

BRACT, BEACTEA, or FLORAL LEAF, brikt (Gr. bracho, I crepitate), in Bot., a modified leaf from the axil of which a flower-bud arises. Strictly speaking, the term bract should only be applied to the leaf from which the primary floral axis, whether simple or branched, springs; while the leaves which are produced on the axis between the breet and the outer envelope of the flower should be distinguished as tractlets or bracteoles. In ordinary descriptions, however, the term bract is used to in-dicate either kind of floral leaf. Bracts are sometimes dicate either kind of floral leaf. Bracts are sometimes large, and similar to the ordinary leaves of the plants upon which they are placed, as in the white dead-nettle. Such bracts are termed leafy, and can only be distinguished from the true leaves by their position with regard to the flower-stalk or flower. In general, however the differ greatly from ordinary leaves. When the flower is sessile, the bracts are often applied closely to the cairs, and may thus be confounded with it.
Again, when bracts become coloured, they may be easily mistaken for parts of the corolla. In some instances they form part of the fruit, becoming incor-

#### Brahma

porated with other organs : thus, the cones of the porated with other organs: thus, the cones of the off and the strobili of the hop are composed of brand arranged spirally, and inclosing fertile flowers and the scales on the firnt of the pine-apple are of the same nature. When bracts grow in a whorl or origin from a single flower, as in the mallow, or a head of flowers as in the daisy, they are said to form an importance of as in the daisy, they are said to form an involume; and when a number grow together, as in the cup of the acorn, they then constitute a cupule. Though the brack is generally a small and inconspicuous organ; it cocasionally acquires a considerable size, and may actually surround all the flowers of a plant so as to completely inclose them when in a young state, as sheathing brack of this description is called a spates; it is very remarkable in the common arum. In the arrasses and sedges little brack called almass and values grasses and sedges little bracts called glumes and palso inclose the essential organs of reproduction. From the word bract several adjectives are formed; namely, bractiscent, assuming the appearance of a bract; bracti'l, furnished with bracts; bracticlate, having little bracts.

BRADFORD CLAY, brid'-ford, in Geol., a member of the Colitic system. It is a blue unctuous clay, occurring at Bradford, and extending for a few miles around that town. It is nowhere more than sixty feet in thickness, and is full of the fossils called Apicorinites.

Bradshaw's Rahway Guids, bride-skew, a well-known monthly periodical, projected by the late Mr. George Bradshaw, of Manchester, and which made its first appearance in December, 1841. It gives official information of the time of departure and arrival of the different trains on all the lines of railway in Great Britain and Ireland, with fares, &c.; also a general steam-packet directory, alphabetically arranged, giving the daily official sailings of all the steam-vessels during the gany omenat salings of all the steam-ressels during the month to and from every port in the United Kingdom; together with a travelling map of the railways of Great Britain and Ireland, and a variety of valuable and local information. The number for March, 1962, contains 237 pages of information on railways and steamboats, and about 60 pages of advertisements, and its sold for streams. The number of this wide heads is sold for sixpence. The success of this guide has induced others to enter upon the same field; but it still maintains its position as the cheapest and most useful of its class. Subsequently, Mr. Bradshaw attempted to do for the continental railways what he had already to do for the continental railways what he had already done for the British, and in 1817 issued the first number of his "Bradshaw's Continental Guide," a work which is still carried on. It attempts also, by giving much general and local information, to supply in some measure the place of a travelling guide for the Englishman on the continent.

BRADYPUS. (See Shoth.)
BRAG, brug (Welsh brugiaw, to brag), a game at cards, deriving its name from the efforts of the players to impose upon the judgment of their opponents by boasting of better eards than they possess. As many persons may play as the cards will supply, the desler giving to each player three cards uning up the last card all round. Three stakes also are put down by each player. The first stake is taken by the best card turned up in the dealing round. The peculiarity which gives the game its denomination occurs chiefly in winning the account table. Here, the breavest ning the second stake. Here the knaves and nines are culled "braggers," and all cards falling into the hands of the players assimilate to these. For example, one knave and two aces, two knaves and one ace, and two aces and one knave, all count three aces. The nines operate in the same way. The third stake is won by the person who first makes up the cards in his hand to thirty-one, with the privilege to draw, or not to draw, as he pleases, from the pack.

as no picases, from the pack.

Bragt, brai'.ji, in Scandinavian Myth., was the son of Odin and Frigga, and the god of cioquence and poetry. He was represented as an old man with a long flowing heard, like Odin; yet with a serene and unwrinkled brow. His wife was Idunna.

Bragna, bray, mg. is the name of the Supreme

BRAHMA, bra-ma, is the name of the Supreme Being in the religious system of the Hindoos. When the terminal vowel is short or elided, Brahma or Brahm, it denotes the essence of the Supreme Being apart from his personal existence. This is not an object of worship by the Hindoos, but only of devout contem-plation. Brahmā is regarded as the great source from which all things have sprung, and into which they will

233

all ultimately be again absorbed. Brahmā, on the other hand, is an individual deity, regarded as the creator of the universe, and constituting, with Vishnu, the preserver, and Siva, the destroyer, the three prin-cipal gods of the Hindoos. Brahma does not seem to occupy now the high place that he once did in the Hindoe system. There are no exclusive worshippers f him, or temples dedicated to him alone; he only re-ives homage in conjunction with other deities. The incoo lavish their adoration upon those deities from nom they expect to derive some immediate advange-upon those who are engaged in preservation or struction. Brahms is usually represented with four sits and four hands, either reclining upon a lote-ee (the emblem of creation among the Hindoos) or ding upon a swan.

BRAUMINSM. (See Hindoolsm.)

BRAHMINISM. (See HINDOOISM.)
BRAHMINISM. (See HINDOOISM.)
BRAHMINISM. TIR, bra-mins, constitute the first or highest of the four castes into which the Hindoos are divided. They are the learned or sacerdotal class of the people. Anciently, all the learning of India centered in them; and many of the Greeian sages travelled thither to be instructed by them. The modern Brahmins, however, are sadly deteriorated from their early representatives; their learning is, in a great measure, confined to their sacred books, on which they write confined to their source with the most rile and licen-subtle disquisitions. Their conduct is characterized by falsehood, dishoncety, and the most rile and licen-tions practices; and yet they maintain a more exten-cive away over the people than the priests of any other mation. Their chief privileges consist in reading the mation. Voda, or sacred volume, in instituting sacrifices, in imparting religious instruction, and in exemption from

magneting rengious instruction, that in exemption from capital punishment. (See Histocorss.)

Brain, brain, is the name given to a soft pulpy substance, which in man and the higher orders of animals constitutes one of the great ceutral masses of the nervous system (which see). As was to be expected, data found in your in which was to refer the day of the found wast noticely daydown in your in whom its property days the found in the control of the found wast noticely daydown in the property days and the control of the control is is found most perfectly developed in man, in whom, with its membranes, vessels, and nerves, it constitutes the whole of the matter inclosed within the bones of the skull, and is, hence, termed the encephalon. In males, the average weight of the full-grown human brain is about 49 or 50 oz.; in females, 44. It varies, however, considerably in different individuals. In a series of 278 cases, the maximum weight of the adult male brain was found to be 65 oz., and the minimum 34; in 191 was 56, and the minimum weight of the adult female brain was 56, and the minimum 31 oz. The brain of the naturalist Cuvier is said to have weighed upwards of \$4 oz., and of that of the late Dr. Abercrombic, 63 oz. avoirdupois. Anatomists differ as to the size or weight of the brain at different periods of life. Soemmerring believed that the brain reached its full size as early as the third year; the Wenzels and Sir William Hamilton fixed the period about the seventh; and Tiedemann, between the seventh and eighth year. Gall and Spurzheim were of opinion that the brain continued to grow until the fortieth year. From a series of observations, however, "it appears that in general the weight of the brain increases rapidly up to the seventh year, then asone slowly to between sixteen and twenty, and then more slowly to between thirty-one and forty, at which time it reaches its maximum point. Beyond that period there appears a slow, but progressive, diminution in weight of about 1 oz. during each subsequent decennial period."—(Quain's Anatomy.) The only animals that possess absolutely a larger brain than man are the aleghant and whale. In the former, it is said to weigh between 8 and 10 lbs., and in the latter it was found. Saveres and to los, and in the latter it was jound, it a specimen 75 feet long, to weigh upwards of 5 lbs. Generally speaking, as compared to the weight of his body, the brain of man is leaver than that of the lower animals; but there are some slight exceptions to this

human brain to the body is greatest at birth, being about 1 to 5 85 in the male, and 1 to 6 5 in the female. At the tenth year, it is about 1 to 14; at the tentate. At the tenth year, it is about 1 to 14; at the twentieth, about 1 to 30; and after that age is averages about 1 to 30 5, with a trilling decrease in advanced his. In general, the size of the brain bears a certain relation to the mental powers of the individual, and a certain amount of it is please. amount of it is always necessary to sound mental action. The brain is divided by anatomists into the cerebrum, or brain proper; the cerebellum, or little brain; the pous Varolii, and the medulls oblongate. The cerebrum occupies the whole of the superior portion of the cavity of the cranium, or skull, and is by much the large portion of the brain, averaging, in the male, nearly 41, and in the female, about 383 oz. The crebellum occupies the lower and back part of the cranium, and is next in size to the cerebrum, weighing, in the male, about 5½, and in the femule, about 4½ oz. The pair Varolii and medulla oblonguta occupy the base of the brain, and together average about 1 oz. in weight, being rather larger in the female than in the male. The former occupies a central position on the under surface of the brain, and is connected with the cerebrum by two cords or peduncles, termed crara cerebri, with the cerebellum with two similar cords, termed crura cerebelli, and is also in contact with the medulis oblougata. This last is that portion of the encephalon which connects it with the spinal cord. It is of a pyramidal form, having its broad extremity turned upwards, and connected with the pons Varolii, while its under portion is united with the spinal cord. The brain is covered by three membranes, two of which, the outer and inner, are termed matres, from the old notion that they gave rise to the other membranes of the body. The outermost of these membranes, from being of firmer texture than the others, is termed the dura mater, and incloses the brain with its appendages, lining also the whole internal surface of the cranium. Its outer surface, which adheres to the bones of the cranium, as the periosteum does to the other bones, appears to be rather rough and irregular; but the inner surface is smooth and shining, and is lubricated by a fluid which is secreted by it. This membrane is the densest and strongest of the whole body, its component fibres interlacing each other in all directions. It sends off several folds or processes, which descend between certain portions of the brain. The principal of these is the superior longitudinal process, or falx cerebri, as fibres interlacing each other in all directions. it is termed, from its supposed resemblance to a sickle or seythe, which extends from the fore to the back part of the skull, and descending into the substance of the brain, divides it into two portions, called the right and left hemispheres. Where it terminates behind, there is a arge lateral expansion of the same membrane, exceeding across the back part of the skull, and separating the cerebrum from the belium : it is called the tentorium cerebelli. From the middle of the tentorium another membranous expansion takes its rise, and descending downwards between the lobes of the cerebellum, terminates at the edge of the foramen magnum, or great occipital hole. It is termed the fulx cerebelli. The second, or middle, of the three membranes, is an extremely thin and delicate substance, and from its fancied resemblance to a spider's web, it receives the name of arachnoid. It is transparent and colourless, and is spread uniformly over the surface of the brain. The third investing membrane, the pia muter, is also very delicate and tender, but differs from the aracknoid in its abounding in blood-vessels, whereas no blood-vessels have yet been discovered in the latter. The blood-vessels with which subtracts of the latter. with which every part of this delicate membrane is covered are the nutrient arteries of the brain. They subdivide and ramify to an extreme degree upon the surface of this membrane, so that the blood may enter the substance of the brain only in very minute quantities. As the pia mater contains and supports the nutrient vessels of the brain, it is not only, like the others, spread over its entire surface, but it also penetrates between all its convolutions, and lines every cavity which it contains. The nervous matter of the brain is composed of two distinct substances, differing from each other both in colour and consistence rule, as in the case of certain species of small birds and One of these is the grey or eineritions subdance, termed in the smaller apen. The proportionate weight of the also, where it forms the enter covering, as in the cerebrum and cerebellum, the certical substance, from its surrounding the inner part like the bark of a tree. The cineritious substance is of a softer consistence than the other, and is composed almost entirely of blood-reasels. connected and sustained by exceedingly fine cellular membrane. It forms an outer covering to the entire surface of the cerebrum of generally about one-tenth of an inch in thickness. The white of medulary sub-stance, which constitutes the internal portion of the scarce, which constitutes the merina portion of the cerebrum and cereblum, is of firmer consistence, and is sumposed of microscopic fibres arranged into laminas and bundles, between which intervening vessels ramify. In the carebrum these fibres run in general, in such a direction as to converge towards the base of the brain. The cerebrum is of an ovoid shape, but ir-regularly flattened on its under side. It is divided into two lateral halves, termed hemispheres, separated from each other through a great portion of their extent by the great longitudinal fissure, into which is inserted the falx cerebri. This fissure, both before and behind passes quite through to the base of the cerebrum; but in the middle it is interrupted by a transverse portion of white substance termed the corpus callonum, which connects together the two hemispheres. Each hemisphere is subdivided into an anterior, middle, and posterior lobe, but it is only on the under surface of brain that these lobes are properly marked off. The anterior and middle lobes are separated from each other by a deep tissure, named the fissure sylvia, which extends obliquely backwards to a considerable depth. The middle and posterior lobes are not so distinctly marked off; but anatomists regard as the posterior lobe that portion of the cerebrum which lies over the cerebellum. The surface of the cerebral bemispheres is not plain and uniform, but presents numerous tortu-ous eminences, named convolutions or gyri, which are separated from each other by deep grooves or furrows, termed sulci. These are generally about an inch in depth, but they vary considerably in different brains, and even in different parts of the same brain; and, indeed, those of one side frequently differ from those of the other. The convolutions are more marked as the brain is hetter developed, and are more numerous and manifest in man than in the lower animals. As the cortical substance of the brain is continuous over the whole surface of the hemispheres, in the fissures as well as upon the convolutions, it follows that the greater the number and depth of these, the greater is the superficial extent of the grey matter which is generally regarded as the seat of all the nervous manifestations, as sensa tion, volition, &c. On slicing away the substance of the hemispheres to a level with the corpus callosum, it will be seen to be formed by the converging fibres of the two hemispheres, whence it has been termed the commissuru magua, or the great commissure of the brain. Under the corpus callosum are the two great cavities termed the lateral centricles, distinguished into right and left. They are very irregular in shape, and are described as each consisting of a body and three horus, or cornua, -the anterior, posterior, and middle. are separated from each other by the septum lucidum which descends from the lower surface of the corpus callosun, and consists of two lamine, between which is the very small cavity of the septum lucidum. It rest apon the fornir, a triangular medullary body, having its apez directel forwards and its base backwards. Posteriorly it is connected with the corpus callosum, and it divides laterally into a posterior cornu on each side, which terminates in, or rather is continuous with the tanta hippecampi, and the hippocampus major and minor. The eides of the fornix slightly overlap the optic thalami, while its inferior surface covers the third ventricle, from which it is partly separated by the velum interpositum. The third ventricle is a small narrow cavity lying between the optic thulami. These last are two large firm oblong bodies nearly an inch and a half long by three-fourths of an inch wide and deep. Anteriorly the optic thalami are continuous with the corpora strinta, and posteriorly they are conmeeted by small peduncies with the Pineal gland, and with the nutes. The corpora striata are two grey pearwith the nutes. The corpora striats are two grey pear-shaped bodies, but internally they are streaked with white matter,—whence their name. In front they are obtuse, and approach each other; but they separate and narrow as they proceed backwards. The Pinsal

gland is a small portion of grey matter about this of a small pea. It was supposed by Descartes a the seat of the soul. The corpora quadrigenties four small white round bodies intimately connec with each other, of which the anterior and super-minance and the matter of the statement of the stat pair are called the nares, the posterior and inferior beamed the testes. The anterior commissure is a named the rests. The anterior commissions as as dullary band uniting the corpora striats, the mic commissure is composed of grey matter, and com-together the two optic thalami, as does also posterio the posterior commissure, which is a rounded white cord. The crura cerebriare two short, thick, rounded cords connecting the optic thalami with the pone cords connecting the optic thalams wish the pone va-robi: They are composed principally of medullary-matter, but in their interior is a semilunar mass of dark grey matter. The cerebellum, or little brain, orm-sists of a body and three pairs of crura or pedunclies, by which it is connected with the rest of the encoplation; and it is not covered with convolutions like the cerebrum, but appears to be formed of a number of lamelle or plates, with sulci between them. When cut across the grey and white matter are seen to be arranged some what in the form of a tree, the white substance forming the stalks, and the grey the leaves; and hence it has been termed arbor vita. The two peduncies of the cereballium connect it with the testes of the cerebrum, and are known as the processus e cerebello ad testes; the infe peduncies—processus e cerebello ad meduliam—pass downwards to the back part of the medulis oblongata, and correspond with the restiform bodies; the middle two are the crura cerebelli, which pass from the middle of the cerebellum, round the outer side of the crura cerebri, and meet in front in the pons Varolii, consti tuting its transverse fibres. The space between the cerebellum behind and the medulis oblongate in front is named the fourth ventricle of the brain, or the ven-tricle of the cerebellum. The pons Varolii, or annular protuberance, is a comparatively small portion of the brain, and occupies a central position on its under surface, above and in front of the medulla oblongata; with which it is continuous. It consists of transverse and longitudinal white fibres, interspersed with a quantity of diffused grey matter. The transverse fibres, quantity of disused grey matter. In transverse sures, with few exceptions, communicate with the cerebellum by means of the middle crura; while the longitudinal fibres are those which ascend from the medulas oblingate into the crura cerebri. The medulas oblongate is that part of the encephalon which is immediately connected with the upper end of the spinal cord, and has an inclination obliquely downwards and backwards has an inclustion obliquely downwards and backwards towards the foramen magnum. It is pyramidal in forms, tapering towards its connection with the spinal cord. It is marked longitudinally by an anterior and posterior fasure, which are continuous with those of the spinal cord, and by which it is partially divided, like the cord, into two lateral and symmetrical haives. On the upper part, however, a new arrangement takes place; for, on each side of the median line, the lateral fissures disappear, and the surface of each half of the medulia presents four eminences or reducing which, commencing presents four eminences or columns, which, commencing at the anterior fissure, and proceeding backwards each way to the posterior fissure, are met with in the following order,—the anterior pyramids, the obvary bodies, the restiform bodies, and the posterior pyramids. From the under-part of the brain issue a mids. From the under part of the brand pass number of nerves, known as the cranial, and pass the base of the skull. They are The following is the proportions of the different sab-stances that compose the grey and white matter of the hrain ---

On the functions of the brain and its several parts, some notice will be taken in treating of the subject Phren-ology (which see). In comparing the brain of man ology (which see). In comparing the brain of man with that of the other mammalin, the most obvious distinction is its much greater size in proportion

## Brein

to the size of the body. In the dog the brain bears an average proportion to the body of about 1 to 120; in the boxes, 1 to 500; in the sheep, 1 to 730; and in the tox, 1 to 300. The convolitions, too, which are so marked on the human brain, are few, or altogether wanting, on the brains of animals. In particular, in animals, the medullary matter of the brain predominates in every part, while the cinertious is deficient. The nervee of sense, too, in animals are usually much more largely developed than in man. In man the olisatory nerve is not one-fourth of the size of that of olfactory nerve is not one-fourth of the size of that of the berse, though the brain is so much larger. In the smaller quadrupeds the comparative size of the brain approaches nearer to that of the human, being in the mouse about a forty-third part of the weight of the animal; but it is composed almost entirely of medullary matter. In birds, the brain is in general a much less complex organ than in mammals, presenting no convoson its surface, and having only a very small quanthe form of the surface, and naving only a very small quantity of cineritious matter. Though its bulk is in general proportionally much smaller than the human brain, yet in some of the smaller birds, as the challinch and the redbreast, it approaches that of the latter. In fishes the brain is yet more diminished; in the chub being only 1 to 842, and in the lamprey 1 to 1.425. It conresists merely of two pairs of ganglia and a single one. The two anterior ganglia or lobes are the offactory lobes, immediately behind which are two others, generally of larger size, called the optic lobes; while behind these is a single ganglion, or lobe, situated in the median line, and termed the cerebellum. Race, Jona, 1854.

BRAIN, DISEASES OF THE.—The brain, which is the most delicate and exquisitely-formed of all the organs notes denote and exquisitely-formed of all the organis-of the human body, is subject to a great variety of dis-orders, most of which will be treated of under their proper heads in other parts of this work, but some of which it will be necessary to notice here. Inflammation is one of the most common diseases to which the brain is subject, and may result from a number of causes, from external injuries, as blows or falls, the symptoms of which may not manifest themselves for many days; from the improper use of narcotics or stimulants, exposure to the cold or the action of the sun's rays, protracted study, excessive joy, or other mental emo-tion; as well as less directly from diseases of the digestive or other organs of the body. It is character-ized by more or less violent pain of the head, with suffusion or prominence of the eyes, the countenance generally tunid or flushed, and delirium or stupor. In the treatment of this disease, general and local bleeding are usually had recourse to; the latter by means of leeches applied about the head, or by cupping. The head is also usually shared, and kept cool by rags wet with cold or iced water. Frequently, in children, inflammation leads to a form of disease known as water in the head, or hydrocephalus (which see). Softening of the brain is caused by the want of a proper supply of nourishment to the cerebral substance, and may arise from various causes. It is characterized by lowmass of spirits, headaches, giddiness, the loss of memory, and at length imbectility and paralysis. Unfortunately, this is a disease which little can be done to remedy, especially when it results from a disordered state of the nutritiont organs themselves, as from disease or obstruction in the arteries which convey the blood to the corebral substance. Frequently it is occasioned by over-anxiety or excessive study; in which case every-thing is to be done to get rid of the predisposing cause. thing is to be done to get rid of the predisposing cause. Every thought, every mental effort, destroys a certain portion of the cerebral matter; and hence, if destruction takes place more rapidly than renewal, a wasting or rottening of the brain is the result. The blood-result, particularly in the aged, are also liable to be raptared. (See APOPLEXY, CONVULSIONS, INSANITY, DELIRATE TRANSMERS, PARLYSIN.)
BRANK OF BRANK, Draik, in Mach., a block of wood

#### Branding

reliway-carriage in which is pluced the brake intended to retard or stop the train when needed. Brakes are sometimes used in the form of bands of metal or leather passing round a wheel, by the tightening of which the necessary amount of friction is produced.

BRANE, OF BRACKEN. (See PERRIS.)
BRANAH LOCK. (See LOCK.)
BRANAH PERSS. (See HYDROSTATIO

(See HYDROSTATIC PRESS.)

Braman Perss. (See Hydrostatic Perss.)
Brambur. (See Rubus.)
Bramburs, brambi-ling (Fringilla montifringilla), also called mountain-fluch. This bird is rather larger than the chaffluch. The tail is forked, and its prevailing colour black, white, and yellow.
Bran, bran, the skins or husks of corn, especially of wheat ground, separated from the corn by a sieve, or boutted. Large quantities of wheat bran are used for making starch. The dyers reckon bran among the monocolouring drugs, and use it for making starch. non-colouring drugs, and use it for making the sour waters with which they prepare their dyes. Bran is

also used as food for horses and cattle.

BRANCH, bransh (Fr. brunche), in Bot., that part of a plant which is produced from a lateral leaf-bud on the primary axis or stem. It is looked upon as part of the stem, and not as a distinct organ. A branch generally produces secondary branches, and these give rise to minor ramifications, called branchlets or twigs. The different modes in which branches spring from the stem give rise to the various forms of trees; such as pyramidal, spreading, and weeping. Thus, in the Italian poplar and eypress, the branches are erect, forming coute angles with the upper part of the siem; in the oak and cedar they are spreading, each forming nearly a right angle; in the weeping ash and elm the angles are oblique; while in the weeping willow and birch the branches are pendulous, from their flexibility. The comparative length of the upper and under branches also gives rise to great differences in the contour of trees, as seen in the conical form of the spruce, and in the umbreha-like shape of the Italian pine. (See STEM.)

BRANCHIE. (See GILLS.) BRANCHIOPODA, bran-ki-op'-o-da (Gr. branchia, gilla, pour, a foot), an ord of small crustacea, belonging to the division Entomostraca, which usually abound in still fresh waters. These animals have thin mouths, furnished with jaws fitted to masticate their food; and their name is derived from the peculiarity which they possess in having the branchia or gills, which are numerous, attached to the feet. They swim freely; but their feet are not generally adapted for locomotion. The antenne, in some cases, serve as organs of motion. While swimming, they keep their reet constantly moving, and thus prevent the water from becoming stagnant.

BRANDENBURG, CONFESSION OF, bran'-den-boorg, in Eccl. Hist., is the name given to a formulary or confession of faith, from the city of Brandenburg, where it was drawn up by order of the elector, with a view to reconcile the differences in the tenets of Luther and Calvin, and to put an end to the disputes occasioned by the Confession of Augsburg. (See Augsburg, Confession SION OF.)

Buandeum, bran'-de-um, a term used in the Middle Ages to signify the silk or linen in which the bodies of the saints, or their relies, were laid. The name was also applied to linen clothes which had been laid on the bodies, and were thus believed to be endowed with great virtues.

BRANDING, brand'-ing (Ang.-Sax.), a mode of punishment formerly inflicted in England for various offences. It was done by means of a hot iron applied to the face or hand. Formerly, all who were admitted to benefit of clergy were burnt with a hot iron in the brawn of the left thumb. The punishment of burning on the hand, however, being found to be ineffectual, it. was charged, by 10 & 11 Will, LLI, c. 23, into burning in the most visible part of the left cheek nearest the nose; but this mode was repealed by 5 Anne, c. 6. 11, how-ever, continued the burning in the hand; and this last was not entirely abolished until 1822, by 3 Geo. IV. c.38. The branding still in force for desertion from the BRAINS, FABLUSHAJ.

BRAINS, or BREAR, bresk, in Mach., a block of wood army is not done by a hot iron, but with ink, gouponspilled by lever or sorew pressure to the circumference of a wheel, to alsoken or arrest the moving power of not liable to be obliterated. The mark is the letter D, a machine, by the production of a large amount of not less than an inch in length, and is marked on the friction. By extension of meaning, it now signifies the left side two inches below the armyti.

# Brandon

Brancon, bron'- don (Gor. brond, fire), a name sometimes given to the first Sunday in Lent, from the conston, which at one time is said, to have prevailed in many places, of the peasants passing through their orchards and vineyards on that day with lighted conches, and threatening to cut down and burn the trees if they did not bear fruit in the coming year

out not near truit in the coming year.

BERNEY, brdn'de, a spirituous liquor, separated from wine by distillation. The word is derived from brantwein, a German word signifying burnt wire. It is prepared from wine in most wine-growing countries; but France, and, most notably, the town of Cognac, in the Charente, has always been considered the great brandy-producing locality. Cognac brandy is esteemed from the absence of a certain flery flavour found in other brandies, which is caused by a parameter. found in other brandies, which is caused by a very small quantity of an acrid oil contained in the skin of the grape. Brandy, when newly distilled, is as clear the grape. Brandy, when newly distilled, is as clear and as colourless as water; but, on being put into oak casks, it acquires a yellowish-brown colour, from dis-solving a portion of the tannin contained in the wood. This colour is generally simulated in inferior kinds by the addition of a small quantity of caramel, or burnt sugar. British brandy, which has been the subject of numerous patents, is an attempt to produce, by factitions means, a spirituous liquor bearing a close resem-blance to foreign brandy. The best malt spirit is blance to foreign brandy. The best mult spirit is flavoured and coloured by various substances, ranging from French plums to oak shavings, each manufacturer liaving his favourite recipe. The quantity of brandy made in France is about 29,000,000 gallons, of which about 3,000,000 gallons are imported by England. Chemically speaking, brandy consists of spirit of wine coloured by tannin or burnt sugar, and flavoured by a small quantity of volatile oil that passes over during distillation.

Branks, brinks, an instrument formerly adopted for the punishment of scolds in England and Scotland. Dr. Plott, in his "History of Staffordshire," says, that it so effectually and safely corrects

scoids, "that I look upon it as much to be preferred to the cucking-stoole, which not only endangers the health of the party, but also gives the tongue liberty twixt every dipp, to neither of which this is at all liable: it being such a bridle for the tongue as not only quite deprives them of speech, but brings shame for the transgression and humility thereupon before it is taken off: which being put upon the offender by

BRAMES.

prames. order of the magistrate, and fas-tened with a padlock behind, she is led round the town by an officer, to her shame; nor is it taken off till after the party begins to show all external signs imaginable of humiliation and amendment." It was of various forms, the party begins to show an external agent magnetosome, humilation and amendment." It was of various forms, but was usually composed of several hoops of iron, one or more of which passed over the head, and one round by the mouth, into which was inserted a plate of iron so as to press upon the tongue. The whole closed behind by hinger, and was secured by a padlock.

Brasenose College, braize - nose, the name of

one of the colleges of Oxford, founded in 1509, by the joint benefaction of William Smith, bishop of Lincoln, and Sir Richard Sutton, of Prestbury, in Cheshire. It was originally established for a principal and twelve fel-lows, natives of the old diocess of Lichfield and Coventry, fulling whom natives of the diocese of Lincoln; and if mone of these be eligible, then the most fit and learned that can be found in the university of Oxford. Eight fellowships were afterwards added, by various benefactors, between 1522 and 1598, subject to various restrictions; but, by an ordinance of the commissioners, under 17 & 18 Vict. c. 81, fire of the fellowships were suppressed, and the rest thrown open. The scholarships and architecture of this college. ships and exhibitions of this college are numerous. Some of the open scholarships are of the value of at least £30 per annum, and are tenable for five years. The Hulms exhibitions, fifteen in number, to which undergraduates of three years' standing are capable of being nominated, are each Worth £120 per annum, besides £35 to be spent in books, to be selected by the principal.

# Brazzes, Monumental

BRASS. (See RUBBLE, Brass, brds (Sax, bras), a compound metal or Brass, bride (Sax, eres), a compound messe or assectationing sine and copper in varying propositions, according to the surpose for which it is to be used; the general composition is, however, two-thirds copper and one-third zine. The use of brass is very ancient, the Romans having been accustomed to make it and at the name of es. Brass was formerly made by the following process:-Copper was first cast in shot-like us process:—Copper was most cast in snot-use managers alled shot copper, by pouring the indiced metal late water. Forty-fire parts of this were mixed with sixty parts of powdered esismine (carbonate of zinc), and a quantity of charcoal powder was added to the whole. The mixture was then placed in crucibles, and subjected to the heat of a furnace for seven or eight hours, and the resulting metal was cast in grante moulds Brass is now generally made by the direct union of its component metals. Brass is of a fine yellow colour, susceptible of a high polish. It is malleable and ductibe when cold, and is more fusible and harder than copper. Great difference appears to exist amongst metallurgists as to the best proportion of copper and zine; and the analyses of specimens of brass of known quality give very different results, varying from 63 to 91 per cent. of copper to 17 to 9 per cent. of sinc, mixed with T or 2 per cent. of tin or lead. The uses of brass in the arts are very numerous. The facility with which it may be cast, or worked in the latte renders it particu-larly valuable for the manufacture of philosophical instruments. Brass wire is used exclusively for pins. Latten is sheet brass, and Dutch metal is brass beaten into thin leaves. Birmingham is the chief seat of the

brass manufacture in England. BRASSARTS, bras'-sarts (Fr. bras, the arm), pieces of defensive armour which pro-tected the arm from the shoulder

to the elbow : when the front part, or outside only, of the arm was protected, the single piece that covered it was called a demi-brassart. Brassarts are sometimes called rere-braces, or arrière-bras. The brassart was worn by the Persians. In Europe, during the Middle Ages, its use, like the other parts of a suit of mail, was general. The term brassart was also applied by the people of that period to any ornament or badge worn upon the arm.

BRASSES, MONUMENTAL, brus'-ees, plates of brass of different forms, but for the most part consisting of representations of the human figure, or highly-ornsmented crosses, let into slabs of stone or marble to serve as sepulchral records of the dead. The slab on which the brass was placed, forming, in some cases, part of the pavement of the church or chapel, and in others, the upper part of an altar-tomb, or the back of the recess in which the altar-tomb itself was sometimes placed under a richly-carved canopy of stone, was carefully hollowed in accordance with the outline of the brass with which it was to be inlaid, to admit of the insertion of the metal sufficiently deep to bring its upper surface on a level with that of the slab. The brass was then hedded in pitch, and fastened to the stone with rivets. The forms in which the monumental brasses were designed were various, and differed greatly in point of decoration and elaborate execution. The figure of the person commemorated by the monument was generally placed in the centre of the slab, the features, armour, folds of the dress, &c., being marked by lines deeply cut into the metal, and filled with some black substance; sometimes a canopy supported by pillars surrounded the figure, adorned with armorial hearings, which were occasionally shown in their proper colours, the metal being out away, and the field or charges being filled with coloured enamels, a white metal being inserted to represent argest. Inscriptions were added, either on labels of brass let into the stone were added, either on tables of brass let min the stone outside the canopy, or on that part of the brass imme-diately below the feet of the figure. These brasses were often gilt or highly poisshed, and when first put down they must have presented a beautiful appearance, the burnished metal contrasting with the stone in which it was inlaid, which was generally of grey marble, or

# Braces, Monumental

sions of a dark colour. On the continent the whole surface of the stone is overed with a plate of brees, and the figures are shown in outline on it, and in this respect the continental braness differ from those found in this country. The most beautiful to be found abroad are in the churches of Belgium and the north of France, formerly known as Fanders, from which country the art is approsed to have been introduced into England by Flomes, artists subsequently to the Normau con-cusset. The oldest brasses known at present in this of rights are seen superquently of the resent in this country are those of Sir John d'Abernoun, at Stoke d'Abernoun, 1377; Sir Roger de Trumpington, at Trumpington, 1377; Sir Roger de Trumpington, at Trumpington, 1377; Sir Roger de Trumpington, 1378; Richard de ington, near Cambridge, 1289; and Sir Richard de Buslingthorpe, at Buslingthorpe, Lincolnshire, 1290. This form of sepulchral memorial was much in vogue until the chose of the 16th century, particularly in the essiern counties; but after this time brasses were less frequently used, falling into disrepute with the magnificent Gothic architecture of the mediaval period, and sysing place, after the 17th century, to the unmeaning mural tablets that disfigure the walls of so many of our churches and cathedrals. Of the thousands of brasses that formerly existed in England little more than two thousand now remain; many were ripped from the slabs to which they were fastened, and destroyed at the suppression of the monasteries by Henry VIII., and many more during the civil war, when the Puritan soldiers of the parliament wantonly destroyed numberless ecclesiastical memorials of bygone times. To show the wholesale manuer in which these valuable monumental records have been made savey with, it is stated in Paley's "Manual of Gothic Architecture," that of the one hundred and twenty brasses that adorned the pavement of York Minster in 1612, only one now remains. In monumental brasses the figure is generally represented in a reclining position, with the hands on the breast as if in practice. the head on a pillow or cushion, and the fect on the figure of an animal, a dog being generally represented at the feet of a lady, and a lion at those of presented at the feet of a lady, and a lion at those of a nobleman or knight. Great attention is always paid to the various details of costume, and, for this reason, these brasses present features of peculiar value to the archamologist and historian, and are invaluable in showing the style of dress and the form of armour and sacwing the style of dress and the form of armour and weapons used at various periods of the medieval his-tory of England. The inscriptions are generally in black letter, or letters of Gothic character, peculiar to the period in which the brass was cut: they are for the most part in Latin or Norman-French. With the revival of Gothic architecture, which is now rapidly supplanting the classic style of building introduced by Christopher Wren, and followed by architects of a subsequent period, the use of bresses as semulchral records has again been introduced, and several me-morials in this form have been lately laid down both in England and on the continent. The following is the process used in taking facsimiles of brasses, or rubbings, as they are called:—White paper, tolerably thick and soft, which is made for the purpose, or cartridge-paper, is laid upon the brass, and rubbed over with heelball. a composition of beeswar, tallow, and lampblack. The incisions in the brass appear in white relief on a black ground, the heelball covering the paper with a dark coating in every part, except where the hollows in the brass offer no resistance to the rubber. Sometimes a paper of a dark colour is used, and the rubbing taken with an adhesive composition coloured with a yellow powder: and, by these means, a far better representation of imparts a metallic appearance to the paper, excepting where the incisions appear, which, from the dark colour of the paper used, resemble in colour, as well as form, sions in the brass itself. The following plan is the in the messions in the orass used. Instituting past in constitute adopted to obtain a durable facsimile, although the process is attended with considerable frombie. The rubbing is pasted on a thin well-seasoned deal board, which has previously been pointed in flat-taned colour to resemble brass as closely as possible. taned colour to resonable brase as closely as possible, and brought to a very smooth surface. The white parties in the paper, corresponding to the incisions in the brase, are then cereduly and away with a graving-tool, and some of the wood below taken out with them. Hollows are then obtained corresponding to those in the brase, which, after the paper remaining on the 239.

## Brawling

board has been damped and removed, are filled with black, or, in the case of armorial bearings conturing in the brase, coloured composition. The scatlest collection of impressions from monumental brases was made by Sir John Cullum, the Rev. T. Cole, and Mr. Craven Crd. It was purchased by Sir Francis Doues, and given by him to the Britiah Museum, where it may now be seen in the print-room.—Ref. Paley's Massact of Gothic Architecture; Waller's Series of Monumental Brases from Edward I. to Elizabeth; Boutell's Monumental Brases of Expland; Oxford Manual of Brases; English Cyclopædia—Arts and Sciences.

Of the cabbage), in Bot., a gen. of plants belonging to the nat. ord. Crucijers, and containing several species, which are commonly cultivated as food for man and cattle. B. rapa is the common turain.

Brassea, brus-si-k (from bresie, the Celtic name of the cabbage), in Bot, a gen. of plants belonging to the nat. ord. Crucises, and containing several species, which are commonly cultivated as food for man and cattle. B. rapa is the common turnip. The species B. campestris is regarded by some as the source of the Swedish turnip; but others consider this vegetable to be a hybrid between B. campestris and B. rapa, or napas. The species B. plaracea is supposed to be the common origin of all the different kinds of cabbage, cauliflower, brocol, and kohl-rabi, the different varieties having been produced by the art of the gardener. Brocoli and cauliflowers are deformed inflorescences; the kohl-rabi is produced by the stem enlarging above the ground into a fleshy knob, resembling a turnip. On comparing the original plant, as found on our shores, with wavy green leaves, no appearance of head, and flowering like wild mustard or charlock, say with the red cabbage or the cauliflower, the difference is astonishing. B. napus yields the rape, code, or colza seeds, from which a large quantity of bland fixed oil, much used for burning and other purposes, is expressed. The cake left after the expression of the oil constitutes the well-known oil-cake used for feeding cattle. The seeds of B. chinemis yield Shanghai oil.

BRATTICE, bratt-tis, a wooden wall or partition made in the shaft of a mine to prevent the eacape of gas or water, or to assist in the ventilation, by creating an unward surpers of hir.

BEAUNITE, brown'-ite, a protoxide of manganese, occurring in Piedmont and Touringia, in dark-brown square octahedrons. It contains 79 per cent. of man-

Bravi, bru'-vi (Ital. bravo, brave), is a name given in Italy to a certain class of individuals who engage themselves for money to perform the most hazardous enterprises, frequently murder.

Bravo! bra'-vo, a term of exclamation, adopted

Brave! bra'-ro, a term of exclamation, adopted from the Italian, avois gnifying excellent, or well done, It is used in English without regard to gender or number, but the Italians use brave for the feminine, and brave for the plural. The superlative is bravissime.

brant for the plural. The superlative is bravissimo. BRAVUMA, bra-voo'-ra(1tal.), in Mus., a term generally applied to a song of considerable spirit and execution; but sometimes it is also applied to the performance of such a song.

Brawling, brand'-ing (Fr. brailler; Belg, brailen, to roar), in Law, is the offence of quarrelling, chiding, to roar), in Law, is the offence of quarrelling, chiding, or unduly, indecorously, or irreverently speaking in a church (including the vestry) or in the churchyard. The sanctity of places dedicated to the solemn offices of public worship has always been protected from violation, and from time immemorial, the courts Christian established in this country have been permitted to take cognizance, not only of actual breaches of the peace, but of the use of violent or abusive words, tending to induce persons to commit a breach of it. There was a time when disturbances in the church were of frequent occurrence, and sometimes carried to great extremities. In the early ages of the Reformation, disturbances were too apt to arise between the statute 5 & 6 Edw. VI. c. 4, was passed, by which it statute 5 & 6 Edw. VI. c. 4, was passed, by which it statute 5 & 6 Edw. VI. c. 4, was passed, by which it shall be lawful for the ordinary of the place where the same shall be done, and proved by two lawful witnesses, to suspend any payson so offending, if he be a clerk, from the entraces of the cliurch, and if he be a clerk, from the ministration of his office, for so long as the said ordinary shall think meet, according to the actual. This act did not greate the offices, sat is sub-

sinced by the occurren law before the statute was masted. A pury, therefore, may proceed either upon the statute or upon the statute the ... In the latter stant, one witness is sufficient to prove the fact. With regard to what may constitute the offence, there is a discretion in the court which would induce it to consider time and place. That might be childing and therefore in a thurth which might not be so in the vestry. The latter is a place for purish business, and the court would not interpose further than might be necessary to preserve order and decorum. Therefore, it has been held, that in a vestry meeting for civil purposes, is a full latitude of discussion must be allowed, more coarse expressions do not constitute the searling. But even there parties must not present manner. But even there parties must not present the only interesting species is H. authelminica, a native of Abysninia, the Howers of which constitute the drug known as Koussoo, which has lately been cur-

drug known as Koussoo, which has lately been em-ployed in both France and England with considerable success for expelling tapeworm. The flowers are apetsious and diosolous, and are imported in a dried state. The mode of administering the Koussoo is peculiar. About half an ounce is infused in a glass of warm water, and taken thus, flowers and water together, on an empty stomach. The flowers contain a considerable quantity of tannia, and an odorous principle to which the anthelmintle property is probably owing.

BRAZIL NUT. (See BERTHOLLETIA.) BRAZIL NOT. (See BERNOLLETIA.)

BREACH, brech (Fr. breche; SRI. brecan, Ger. bre-

shen, to break), in Mil., a term used to denote an open-ing made in any part of the rampart of a citadel or forby a continuous cannonade directed against that particular part by the besieging force, in order to obtain an entrance over the ruins and debris of the shattered wall. As soon as the breach is effected, and the stones as well as the rubbish and earth behind the wall are brought by the firing into the form of a rough inclined plane, a storming party is told off, and the works are carried by assault. To effect a breach, the breachingbattery is brought as close to the walls as circumstance will samit, that the fire may be directed in a line almost perpendicular to the face of the rampart. Sometimes the desired purpose is attained by mining. The attack and defence of a breach is obstinately conducted on both sides, and is always attended with considerable bloodshed and loss of life. At the siege of St. Schattan, during the Peninsular war, about 100 feet of the curtain between two bastions was brought down after a fire kept up for nearly seven weeks, during which 13,000 shots were fired; it was then taken by storm, the assaulting column being under the com-mand of General Graham, afterwards Lord Lynedoch, August 31st, 1813. The French gave the storming-column a warm reception, having defended the break with strong cheraux.de-frise, consisting of sword-blades and hayoners fastened to beams of wood, and shells, and powder-barrels, which were fired by means of a train communicating with them, while the rugged slope was strewn with planks and pieces of wood, studded with spikes and nails and sharpened iron. Under the system introduced by General Toditeben at the siege of Sohastopol, of constructing earthworks on an extensive scale, for the defence of a besieged town, a breach can be more readily repaired, although the enormous projectiles that can be hurled against any defensive works from the rifled cannon of the present stay, will render the formation of a breach a more sear task, and sooner accomplished than it was

Somethy. Bred (Ger. brod, or, Ang. Sax. brayed, from broy, to pound in a mortar), a very important article of food, made by baking, in an oven or pan, a mass of dough composed of the flour of different grains mixed with water. Bread has been used as food by manking from the very earliest times. The necessities of man's mature have been the origin of many of our useful aris; and the discovery that grain when moistured and afterwards heated could be made into a

palatable, darable, and autritious food, considered a very important one. This the extiest form in which break was not step would be the pounding of the re stones, and the formation of four; the la-te the balding of lowes or fermented. be the baking of course or terminate mentioned in the Sariptures that Abraham leavened bread; and also that, in the three leavened bread was used (Rxod, xil, 15). The saries of the sar unlesvened bread is a very simple matte the ordinary sailor's biscuit is an exam BISCUIT); but the baking of leavened or the bread is a complicated although common Bread is made from the flour of any of the pread is made from the flour of any of the enrealy-wheat, cye, barley, oats, &c.; but as wheat is the most nutritious grain, it is most generally used. It is also the only grain from which a light porous bread oat is made. Wheaten dough, cleared from the brain of husks of the grain, consists of water, glaten, starting sugar, and dextrine, or British gum. If dough is left by itself in a temperature het man and with the sugar, and destrine, or British gum. If desigh is left by itself in a temperature between 80° and 120°, formentation slowly takes place. The starch is first converted into sugar, and then into alcohol and carbonid acid; if baked at this period, a light bread with as agreeable relish is procured; if, however, the temperaturin goes on too long, acetic acid is formed, and a heavy bread with a sour taste is the result. In order to procure a more perfect fermentation, a leaves is employed. This leaven is either a piece of dough in a fermenting state, or years, a substance tradecod is fermenting state, or yeast, a substance produce beer while in the act of fermentation. Yeast is: generally used, as it is quicker and more certain its action than the leaven of dough. In order to be loaf of bread, a small quantity of yeast is well kneaded into a mass of dough, and allowed to remain in a moderately warm place. Fermentation begins to take place; and, as the carbonic acid and alcohol are disengaged, they struggle up through the elastic mas and the loaf begins to "rise." It is then put into it oven, where the increased heat causes the further ar pansion of the inclosed gas and vapour. The process of fermentation is soon checked by the high temperature, and a light porous bread is at last produced. Well-baked bread is known by its lightness, and the regularity of the size and distribution of the small ils formed by the carbonic acid gas and alcohol Home-made bread is mostly sweeter, lighter, and more retentive of moisture than bakers' bread. recentive of mosture than takers creat. The following process is largely employed in the trade;—Mashed potatoes, water, and patent yeast are mixed together to form a ferment. After the quantity of four required has been put into a trough and mixed with water, not too cold, the ferment is added and well stirred with the hands. It is then strained through a sieve, more flour added, and the whole well mixed; after a little flour is sprinkled over the top, the dough is allowed to stand for five or six hours. During this time, the sponne, as the dough is called, rises twice. The first rising is allowed to break and fall down; but upon the second rising, just before breaking, a quantity of water is poured into the sponge, together with salt, and sometimes slum. The whole is then well mixed together again, and, after standing for some time, is divided into the necessary sizes and conveyed to the over: into the necessary sizes and conveyed to the over. The amount of potatoes added to the flour in this process is very small, the proportion being 3 has of potatoes to every 280 hs. of flour; but some sheep-bread bakers use a much larger quantity. It is expensionally called fruit in the trade. It is a comparatively harmless adulteration; but the alum, or styf, is a more objectionable addition. By using alum, a meak whiter quality of bread is produced; how this bleaching operation is effected is not thoroughly understood. Alum also causes the loaves to break from each other with a much smoother surface than when break is baked without it. Common sait is also used for the same purpose; and on the continents small guardities, of sulphate of copper have been used by the bakers. It not only produces a white break from inferior kinds of flour, but adds greatly to the retentive capabilities of break for water. Sulphate of copper has neverbeen discovered in English break. Besides being much adulterated with mashed potators, rice flour; often found in break. Rice flour absorbs and retains a large quantity of water. Carbonate of magnetia is Alum also causes the loaves to break from each oth

bank of stone, so placed as too sea, pajore the entrince into a s Plymonth Breskwater is a very s of this kind of barrier. The sound harbour of Plymouth was very a harbour of Plymouth was thenever then the south-west. Many ships significant the south-west. Many ships significant the transfer of the south-west. lost through its exposed state and through its exposed state. Landon breakwater was inst proposed by Lord to Lord Howick, then first lord of the 1800: but it was not until 1812 that the and Whichy's plan was adopted and the menced. The mode of proceeding was that of de in mid-channel large blocks of himestone carrain a neighbouring quarry. These stones were to the site of the breakwater in ventels of p construction, having openings in the stern, out of in the stones were cast into the sea. The large at used for the construction of Plymouth Breaks were conveyed to the spot whence they were dropped into the sea in fifty three versels of alle fifty tons each. From one of these vessels a load fifry tous was discharged in about three house. In the vear 1812 the whole of this fleet discharged 18,015 tons of stone; in 1813, 71,198 tons were deposited; in 1814, 239,490 tons; in 1815, 2\*4,207 tons; and in the year 1816, 206,033 tons. Up to this period the guan of deposited stone amounted to 898,983 tons; but it amount was subsequently raised to above 1,000.6 amount was subsequently raised to above 1,000 tons. The proportionate dimensions of the depo blocks of stone were nearly as follows :-

Of five tons and upwards ...... 12,760 tons, Of three to five tons 150,593 ...
Of one to three tons 509,705 Of one ton and under ...... 433,904

For quarrying of this stone about 2s. 5d. a ton wash and for the carriage of it is, 10d. was paid. Assorbing to the best calculations, the cost of each ion of the sunk in the breakwater amounted to about \$4.15 The total estimate for the completion of this break water was originally £1,524,000, but the sums bitherto expended upon the work amount upon the whols £1,562,639. The engineer of this breakwater was 1 £1,562,639. Bennie, who died before the undertaking was com-pleted. The breakwater, which is thrown screen the middle of the Sound, lies almost due east and west, and is completely 'soluted, leaving a chaquel of half mile on either side. The centre porties, was straight, is 1,000 yards in length, and there in wings 350 yards long respectively, which incline to the north at an angle of 120 degrees to the at portion. The breakwater stands three feet abo portion. The breakwater stands three feet above level of the highest spring tide, is 120 yards by the base, 16 yards at the top, and has an average of 14 yards. The sides, which base a consideration, and the top are faced with masonsy. ciency of the breakwater as a protection to the has often heen proved, and two years after it we menoed ships of all sizes began to take shelter it, although only 600 yards of the work week visible at low water. The breakwater at Civil. which was constructed by Trajan about s.p. 10 markable, as it appears, according to Pliny il that it was made in a very similar man Plymouth.-(Plin., lib. vi. epist. 31.) Fo water, which was finished in 1861, form rotection to shipping. It is comp from the neighbouring promoutors. The work, which was almost entired convicts, was commenced in 1847. Cherbourg Breakwater is d, and has cost, since 258 WORK SI IDS KEEL, MILL HOR OUT, MINDS HER OF SOURCE IN WAS COMES AND SERVICE OF SOURCE OF SO tree, the convex to the north, across the he bay, leaving a passage 1,000 yards wide aids. It is principally built of grant- and In 1859 Mesers Bichardson and Jaffrey, neers of Durham, completed an unvention relating protective sea-works of various kinds, as, for inof defence of the coast against the action of the for the defence of the coast against the action of the wind and waves, or for the protection of shipping Plate XXII., fig. 1, represents, in side clevation and partial vertical section, a breakwater according to Meters. Richardson & Jaffiev's plan, ig 2 is a corresponding plan, and horizontal section of the same. In constructing a harbour of refuge, the investions build a series of iron towers (A A), which wants having demonstrad in the sea at a certain distance. upon being deposited in the sea at a certain distance stunder, extend outwards and partially in lose the required extent of sea-room. The figure of these ers is mrcular in transverse section, wide at the and tapering upwards, and they are constructed of malleable from, but, instead of these materials, asy be built of stone or timber, and made solid thing to the method to be later described. When the towers are formed of metal, a traming of perpendi ouler and preserves circular or cylindrical libs is bolded together, so as to form a skeleton figure of the edstermined shape. Upon this internal framing sets of cast or wrought iron are riveted or otherwise sured. The height and size of these towers must mend to a great extent upon the depth of water and the position of the work. The fowers being sunk at the desired spot, the water contained within each is primped but, and the interior filled with masoniv, the blocks of stone being previously cut to the required shape on shore. In this manner the work may be carried on with great rapidity, the coment used in the building stations being meanwhile wholly protected from the Instead of using stone as the material for filling in the towers, concrete, "beton, or other hard-drying plastic cement, may be moulded unto blocks of the required figure on shore, and dried these blocks, when litted into their proper pisces within the power, are to be comented together with a little maintage of the coment or plastic insternal used for moulding the blocks The inventors in some cases give the preference to another mode of proceeding, via to all the whole of the interior of each tower with "beton," or hydraulic cement, as shown at B, fig 2, which cement bondifying within the tower, the whole frems a compact and solid mass, capable of withstanding the waves of the sea after the removal or wearing away he external plates of metal. In hea of this solid a of "beton," a filing-in may be used composed the of "befor," a filting in may be used composed "befor," having a central mass or core of slar, as C. fig. 3. the interstoce of which may be filled up th liquid, so as to form the whole into a solid mass is operation of illing up the towers with miscorry or its plantic material is materially facultated by the measurement which the summits of the towers afford refliging which the summits of the towers afford to once laying down a permanent gangway of road though the tower to the other, along which materials Then this down to the other, along which materials implantation may be conveyed with nearly the same its act on shore. Instead of constructing the towers was, they may be built wholly of stone, a suitable non-being sumit over the epot where the tower is to rected. This water having been pumped out of the con, the work may be conducted with great rapid-may be appeared by the configurations towers. All

holted together, open restant between the contiguous various Another mode of constructing th them of cast-iron pipes or of malles addition to the protective action there is another and highly important a ing the use of them in harbours and of works, which is, that from their open they prevent the silting up or accumulations do the harbour, as the tide has fr egress through the open screen, so that depth of water is miintuined. The count depth of water is miintuined harbours, piers, or quars upon this plan sessels approaching close up to the toners; thus ing the waste of room and inconvenience at long sloping sea-walls of the ordinary consta situations where a rigid or impermeable requisite, the intermediate spaces between the are tilled to with a wall of masonry, as at FE formed of blooks of "heton" or concrete as together, and defended, or not, on the outer crises aide, by a lattice work of timber or metal. For structures the towers mas either be the simple tower sunk into its proper place, or it may or wholly fuled up with mesonry or other and According to this system of const breakwaters or other similar exposed works, is as possible to carry out such works in a magnes more economical, no portion of the materials engigles being wasted. In the year 1828 a commission appointed by the American Government recommended. York harbour to the mouth of Chesapeake Bay th nors neroour to the mouth of Chesapeate hay there was no good place of shelter along the cosst for vessels exposed to easterly gales. The entraines of Delaware Bay on the south side was nadged the most advantageous point for constructing a harbour of refuge, though it was both open to the most dangerous gales from the Atlantic and those across the waters of Delaware Bay from the north-rast by the north round to the west. The place is also expe to the fie ds of see that are brought down by t to be he do to toe that are drought down by the each tide during the winter. The plan of the breakwater was consequently designed to guard against dangers from these different directions. It consists fixes of a straight mole 1 203 yards long, in water of five to sat fathoms deeth, the sea slope being curved after the curvilinear figure assumed by the breakwater at the curvilinear figure assumed by the breakwater at Cherbourg The work was commenced in 1829, under the direction of Mr Strukland, and in 1834 it was so far advanced that vessels found a protection behind it The stone used in this work was obtained from a variety of sources-some tiap rock from the Pales in the Hudson river, green-tone from the southern part of Delaware, and guess from different quarries in the same state. These rocks, though swares ng a weight of 175 lb to the cubic foot, were mentioned to nithstand the action of the sea in the course of the construction of the moles. During the winter season those upon the surface of the work water more season more upon the strates of the wark ware were or less displaced, and a large piece of seven weight was moved, in one storm, eighteen feet in must slope of the nee-breaker, down which it lost At the same time, about 200 tons of a leavy stone, which had been thoroughly wedged compacted together, was form up and awent over the inner side. In the United States there have a been constructed breakwaters of considerable mag tude upon the great northern lakes, for the prot ton of harbours, as at Buffelo and Clewsland. tude upon the great novier names, up and a tion of harbours, as at Buffslo and Clevelai Lake Eric, and Chicago, on Lake Michigan. first-named is a massive pay of stonework driven in rows into the sand are sometimes confor the construction of breakwaters; but they little service in exposed attations.—Bot Riph Dana's New American Cyclopadia; Eng. Esc. of Arts and Sciences; and Mechanic's Mag.,

Feld breath may also arise from a diseased state of the lace

may also arise from a diseased state of the lungs. Where it cannot be remedied, it will be well for the patient to chew a little cinnamon occasion-

pared for to take some of the aromatic purpose.

Take real forcess (Sax. brath, breath; Lat. figure, figure)—if s clean surface of glass or any other pulished substance be written on with the surface be

any other polished substance be written on with a binot-pointed instrument, and the surface be afterwards breathed upon, the characters written with become visible; or if the surface be first breathed upon, and the characters then marked upon it, they can be again made perceptible by breathing again upon the surface. These form what are called breath figures, which may be produced in several ways. In 1842 Moser informed. Humbridge that it is a very bodies be because for the surface. Humboldt that "if any two bodies be brought sufficiently near each other, and face to face, one of them impresses its image on the other;" thus, if a coin be placed for any length of time upon a piece of polished metal, the metal will retain an impression of the coin, and exposure to the vapour of water, iodine, or mereury, will make it visible. A glass used to protect an engraving will receive an impression of the engraving on its inner surface, although it is not in absolute conset with it. Engineers have remarked that those parts of machines which are in contact with, or near such other, rapidly and easily impress themselves upon each other. guet has stated that the letters and inscription on the sak of the inner cases of his watches have been often

found impressed on the inside of the outer cases. Perfact impressions of objects may be produced by means of electricity; and remarkable varieties of roric figures

est be impressed upon glass surfaces by means of a small electrical machine, a Leyden jar, and a discharging rod. Photographers know that the state of the breath has a very considerable influence on the plates

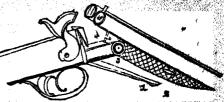

they use; and its effect upon other arts has been re-marked in the Dict. des Arts et Métices, Lyon, 1801. Artista in enamel-painting are taught that no one should be sllowed to approach their work who has been taking mercurial medicines or eating gartic. Buzocia, brech'-che (Ital., a crumb or fragment), in Geol., a rock consisting of augular fragments bound or comented together by calcarcous, ferruginous, or siliclous matter. Such a rock differs from a conglomerate,

or puddingstone, in having its component irragments irregular and sharp, whereas the peobles of the latter are rounded and water-worn. (See CONGLOMERATE.)

A central pivot round which the movement is made. 4. A notch, which allows the barrels to be so placed as to be easily loaded at the breson whom a hook is liberated. 11 is a pin which, when struck by the hammer, transfers the blow to a cap inverted in the cartridge. the cartridge.

BREEDING, brede'-ing (Sax. bredan, breden, to bred is the method of multiplying and improving the in of domestic animals rapidly. Great attention has paid to the subject of breeding since the commipaid to the surject of oreging ance the commence ment of the present century, one motable result being that within the last thirty years the weight of matter produced has nearly been doubled in proportion to the number of sheep. If a proper supply of food is far nished, any breed of animals will perpetuals their the various breeds of wild animals are instances of thi But when assiduous attention is paid to the breeding of domestic animals, varieties are produced which are more useful and profitable than the wild breeds, on account of particular properties which they possess. The first point of importance in breeding the selection of the animals with which to propagate a useful race. These should always be the finest animals possible; and great improvements in the stock existing on a furm are often produced by the introduction of on a furm are often produced by the introduction of males of a superior quality. In breeding, the purposes for which an animal is reared must always be taken into account. The breeding of horses has occupied attention much longer than that of overs and shears. One class of horses is bred for speed, another for one-minimum of the production of the produ veying rapidly between different places, another for mere labour, or to assist human strength. By attention to the breeding, great excellence has been arrived at in each of these varieties. Strength and speed in their extremes are never present in the same animal; but a combination of the two is most useful. (See Horse.) The properties desired in sheep and over are very different from those required in horses. The fleeces and hides of the former are used as raw materials for manufacture, and their fiesh as food. The breeder of oxon and sheep sometimes has the perpetuation of good qualities in view, and cometines the production of the largest quantity of best or mutton possible. Since attention has been paid to the breeding of these animals, they have been sent to market at ing of these animals, they have been sent to market as much earlier age. Sheep and ores which have been thus improved are both distinguished by small heets, and lib ones, short legs, and thus akin. Wild animals have precisely opposite qualities. In breeding any domestic animal, a near relationship should always be avoided. The principal points to be charged in breeding are as follows:—The kind of animal from which the breed is desired should have distinguishing posits, which ought always to be kept in rise. The most

nate kind should be bred dis

or more families of the name cind should be bred distinct, buly occasionally crossing them together. The more improved a based becomes by this mean, the more infrared becomes by this mean, the more infrared becomes the adequate by the mean, the more infrared becomes the adequate of the unimals by which it continues it, and vary often, on account of this difficulty, a highly amproved inseed will degenerate. (See Or. Samer.)

BRINKI, breefe small cinders mixed with ashes, used as held in tirick-kilns. The word is apparently a corrunting of the Franch word braits, live out.

BRINKING (A. breezes), in Mar., a shifting wind that blows thating sertain hours of the day and night, from the state of the first alternately; and is only sensibly felt near the neart. The sea-breeze generally rises about 9 in the meaning, proceeding slowly, in a fine curl on the water, towards the shore, gradually increasing until 12, and dies away about 5, when it is succeeded by the land three, which also continues increasing until mittight, and is again followed, in the morning, by the sea-breeze, which also continues increasing until mittight, and is again followed, in the morning, by the sea-breeze, Breezes differ from etesia, or trade-winds, issummed as the former have their periods daily and much as the former have their periods daily and

magnity, and are only found near the coast, while the latter are annual, and blow at a distance from land.

Bernow Laws, bre-hon (Lat. brehonicæ leges), were the general rules of law observed in Ireland by the Breions, at the time of the conquest of that country. by Henry II. The Brekons were the provincial judges among the ancient Irish. By some writers they are said to have been a distinct tribe, baving competent lands allowed to them in inheritance; by others to have been hereditary magistrates attached to various tribes. Their decisions were generally made in the open air, on the tops of bills; where particular spots are frequently called, to this day, Brehon chairs. In criminal cases the Brehon had the eleventh part of all the fines, which could not but be considerable at a time when murders, rapes, robberies, and the like offences, were only applect to pecuniary commutations. When the conquest above mentioned was effected, the laws of England were received and sworn to by the Irish of England were received and sworn to by the Irish mation assembled at the council of Lismore; and afterwards. King John, in the twelfth year of his reign, went into Ireland, and carried over with him many able asges of the law; and there, by his letters patent, in right of the dominion of conquest, is said to have conducted and established that Ireland should be governed by the laws of England, which letters patent Sir Edward Coke apprehends to have been there confirmed in markingent. But to this ordinance many of the stable of the council and the cou firmed in parliament. But to this ordinance many of the Irish were averse to conform, and still adhered to their Brehon law; so that both Henry 11I. (A. R. 30; 1 Rem. Food. 442) and Edward III. (A.R. 5; 3 Prym. Rec. 1218) were obliged to renew the injunction; and Edwards in a parliament holden at Kinkenny, 40 Edward III., under Lionel, duke of Clarence, the theu lieutenest of Ireland, the Brehon law was formally abolished, it being unanimously declared to be indeed ne law, but a lewd custom crept in of later times; and yet, even in the reign of Queen Elizabeth, the wild native still kept and preserved their Brehon law, which opensor describes as being "a rule of right unwritten, out delivered by tradition from one to another, in which obtainings there appeared great show of equity in determining the right between party and party, but in many things repugnant quite both to God's laws and many. The latter part of this character is slone accribed to it by the laws of Edward I. and his grandson. Spensor was wrong in speaking of the Brehon likes as an impristen code; for several fragments of laws as an invertion code; for several fragments of them are still in existence in public and private hisraes in freiand, Belgium, and England. A translation of these laws has for the last eight or ten years been in the second of preparation for publication at the second of manuscripts of the Leges Brebonius of manuscripts of the Leges Brebonius brought significant were those in the Chandos collection, containing twenty-two sheets and a half closely written, hilloft abbreviated words, and not very legistrates, hilloft abbreviated words, and not very legistrates. Because and some modern writers have stigmanised these laws as most wicked, because murder was empounded by bribery. But the principle of peculary compensations for all orimes pervaded equally the tables is a sea those of all the German nations.

(P), built of stone and lined with afuces. Into these become so systematized, that there are men who make the beer is let down when sufficiently fermented, and strength of beet-doctoring. Amonosi the humis kept tall wanted. These vaults are used at Mesers Whitbread's brewery, instead of the great store-vate of which we have already spoken, and are its some temperate preferable, because they preserve a great speakity of temperature, being beneath the surface of the sarth. Figs. 1 and 2 represent the multicilers, or machine for bruising the grains of muit. A is the bopper into which the malt is let down from the maitioft store, and from this the malt is let out gradually through a sluice or sliding-shutt's (a), and falls between the rollers B, D. A screw (E) is lapped through the end of each of the mon frames which is cave the rollers, and by these scraws the rollers may be made to wors closer to each other, so as to bruse the mait 'u a greater degree. G is the shaft by which one of these rolless is burned, and the other receives its motion by Bixed at the apposite ends of each of the rollers. d is a small lever which bears upon the teeth of one of Same cog wheels, and is thereby lifted up every time a cog passes. This lever is fixed on the extremity of an axis which passes across the wooden frame, and in

a regular trade of beer-doctoring. Amongst the hundreds of nugledients used for this purpose may be reckoned quasas, gent in, and wormwood, to give bitterness, ginger, orange-peel, and caraway, to impart pungency; alum and blue vitriol, to enable the beer to preserve a froth; head; cocculus indicus, aux vomes, and tobacco, to intoxicate; and salt, so promote thirst. Tome-brewing is very much certified on in England, and the processis employed are smiler to those described, the apparatus employed, however, as simpler, and often very rough. Many other countries, and Bavaria in particular, brew in different manners,

and from different substances.

HRIBERY, brider ce (from Goth, bry fix, Sax. bredfix, a bribe), that is, a perverting the or gift, something added to the simple demands of justice, with a riew to influence its decisions, a boon to prevent honesty, given to the worthless in high places. (See "Minutes of Fudence before the House of Commons," art Irish Magistracy.) The Glossey to mons," art Irish Magneracy.) The Glossary to Chaucer explains bribone as a thief, bribon, to decoy; while a bribe is probably what is given to a began, what is given to a began, what is given to an extortioner or olsest. To bribe is to corrupt by gifts, to hire; bribery, the crime of giving or taking rewards for evil practices. Bribone in some of our old statutes signifies one that pillers other nien's givids. (28 Edward II. o. 2.) Rethery is an offence against public pusition, and is committed when a judge, or they preson cohorenced in the administration. as axis which passes across the wooden frame, and in the indicate the probability what is given to a began, as axis which passes across the wooden frame, and in the indicate of it has a lever (c, ii., 1) bearing up a trough (c), which hangs under the opening of the frame of giving or taking rewards for evil practices. Bribour longer A. By this means the trough b is constantly longer, and shakes down the malt regularly from the chapter A. It is the lower hand of the men's glode. (28 Edward II. o. 2.) selling a man's rote in the senate or other public as setting a man's rote in the senses of diam' processes assembly, as for the bestering of common justice, yet, by a strange indulgence in one instance, it tankly encouraged this practice, allowing the magintains is receive small presents, provided they did not in the whole streed one hundred crowns in the year, not whole exceed one insuficed arows in the year, not considering the insulating nature and gigantic progress of this vice, when ones admitted. Plate, therefore, more wisely, in his ideal republic (De Leg. 1, 12), orders those who take presents for design their duty to be punished in the severest manner; and, by the laws of Athens, he that offered was also prosecuted, as well as he who received a bribe.—(Pott. Antiq, h. 1; c. 23.) In England this offence of taking bribes is punished, in inferior officers, with fine and imprisonment; and in those who offer a bribe, though not taken, the same. But in indees, especially the not taken, the same. But m judges, especially the superior ones, it has been always looked upon as so hemous an offence, that Thomas de Wayland was banished in 1288, and William de Thorpo, chief justice of the King's Bench, was sentenced to be hanged for it in the reign of Edward III. Blackstone says he was actually hanged, but Lord Coke (3 Inst. 145) denies that he was or could be hanged for this offence, though he was certainly condemned to this punishment; and the cites the parliament rolls, 10 Ric. II. 24, to show that he was then purdoned and restored to all his lands, By a statute of Henry IV. all judges and officers of the king convicted of bribery were to forfeit treble the bribs, be punished at the king's will, and be discharged from the king's service for ever; and some notable examples have been made in parliament of persons in the highest stations, and otherwise very eminent and able, but contaminated with this sordid vice. Lord (Bacon) Viscount St. Albans, lord high chancellor, was fixed £40,000, and sent to the Tower, declared incapable of any office or employment in the state or within the verge of the court; but part of the sentence was afterwards remitted. Mr. Walpole, secretary at war, was sent to the Tower in 1712; and Lord Strang-ford, in 1784, was asspended from voting in the Irish House of Lords for soliciting a bribe.—Ref. Blackstone's Commentaries, by Stephen, vol. iv. b. 6, c. 9, s. 18; and see Dent. xvi. 19, and 1 Sam. viii 3.

BRIBERY IN ELECTIONS FOR PARLIAMENT.—The

offence of bribery in elections for members of parliament is one at common law, and the offender may be proceeded against by indictment. Besides the Corrupt Practices at Elections Bill (15 & 16 Vict. c. 57), the act 17 & 18 Vict. c. 102, which was passed in 1854, and consolidated and amended the lawerelating to bribery, treating, and undue influence at elections, contains some stringent provisions for securing the freedom of elections. By the latter act, an offender is made guilty of a misdemeanour, and, in addition, liable to forfeit £100 to any person who shall sue for it, if such offender shall, directly or indirectly by himself or any other person on his behalf, give, lend, or agree to give or lead, or offer, promise, or promise to procure, any money or valuable consideration, or any office, place, or employment, to or for any voter, or to or for any person in behalf of any voter or any other person, to induce any voter to vote or refrain from voting, or corruptly do may such act as aforesaid, on account of any voter having voted or refrained from voting at any election, or to or for any person, to induce such person to procure, or endeavour to procure, the return of any person to serve in parliament, or the vote of any voter at any election. The same liability extends to every person who shall, upon or in consequence of any suit, gift, loan, offer, promise, procurement, or agreement, produce, or engage, promise, or endeavour to procure, the return of any person to serve in parliament, or the vote of any voter at any election, or who shall advance or pay, or cause to be paid, any money to or to the use of any other person, with the intent that such money, or any part thereof, shall be expended in bribery to be paid, any money to any person, in discharge or tenayment of any money to any person, in discharge or recognisest of any money wholly or in part expended in bribery at any election. This enactment is, however, mut to extend to any money paid, or agreed to be paid, for or an account of any legal expenses band fide insurred at or concerning any election. And any person

who shall, before or during any elections, directly or midirectly, by himself or by any other person on his behalf, receive, agree, or contract for any name; gift, loan, or valuable consideration, office, pines, or employment, for himself or for any other person, for voting for himself or for any other person, for the person of the consideration, office, pines, or employment, for himself or for any other person directly or indirectly, by himself or by any other person on his behalf, receive any money or valuable consideration, on account of any person having voted or refrained from voting, or having induced any other person to vote or to refrain from voting, shall be guilty of a misdemeanour, and also liable to forfeit 210. See, defines what is undue influence. The member returned through bribery is also liable, upon petition, to be disposessed of his seat. The taint of bribery seems to have affected of his seat. The taint of bribery seems to have affected of exadicate it. The assumed virtue of the House of Commons is from time to time, and frequently at an enormous expense, vaunted and puffed up by most taile proceedings, in the vain attempt to show its incorruptibility; and its vanity has been appeared by an occasional disfranchisement of some poor borough, whereas others of more importance have appeared to defy its power, or have escaped from the effect of its censure. More than a century ago, we find Mr. Justice Blackstone acknowledging and lamenting the extent truly distinguished and sagacious judge has left on record, in his Commentaries, this expression of his censure. More than a century ago, we find Mr. Justice Blackstone where the head of the subjection, which, in all probability, would be much more effectual than administering it only to the electors."

And that eminent and "pright judge, Mr. Justice Coleridge, in his edition of the same Commentaries, her expressed his own opinion thus:—" It is probable that no measure will be effectual till the simple and obvious consuggested by the author be adopte

BRIBER OF OFFICERS.—In the Customs and Excise, officers and persons making collusive seizures, or taking bribes, are, by the 16 & 17 Vict. c. 167, s. 282, liable to a penalty of £500, and incapacitated from serving her Majesty in any office, civil or military; and every person offering the bribe is liable to a penalty of £200. In the court of Chancery, officers taking any fee, gift, gratuity, or emolument, other than what is allowed or directed to be taken by them, are, by 3 & 4 Wm. IV. c. 94, s. 41, liable to a penalty of £500. In Municipal Elections, by 5 & 6 Wm. IV. c. 76, s. 54, if any person who shall have or claim a right to vote in any election of mayor, councillor, auditor, or assessor of any borough, shall sak or take any money, or other reward, by way of gift, loan, or other device, or agree or contract for any money, gift, office, employment, or other reward, to give or forbear to give his vote in any such election; or if any person, by himself or any person to give or ferbear to give his vote in any such election; he shall by any gift or reward, or procure, any person to give or ferbear to give his vote in any such election, he shall, for every such defence, forfeit £50 and costs of suit; and, on being convicted of the offence, shall be disabled from voting in any election in such borough, or in any municipal or partial and shall for ever be disabled to hold, exercise, or enjoy any office or franchise to which he shall be or become entitled as a burgess of such borough; as if he were naturally dead.

were naturally dead.

Bugors, brike (Fr. brique).—The material used in making bricks is clay, which is worked into a plastic state by kneading, and then moulded into a rectangular form, if inches long, if wide, and very nearly 3 inches thick. These pieces are afterwards dried, and then hardened by baking in a kingr in stacks. Bricks have been used in building from a very early period; the tower of Babel was a structure of kiln-baked dricks, and the imposing buildings of Nineveh and Babylon,

Brickwork

reared on huge mounds of many scree in extent, and the pyramids of Egypt, were all built of the same material. The Greeke and Romans also used brioks in many of their public works; and it is probable, from the unceriptions atsamped on those of Babylsn, and the various marks on those of Greece and Rome, that all various marks on these of Greece and Rome, that all were formed in moulds hafter they were hardened by the sun or fire. One peculiarity to be noticed with respect to the Roman bricks, many of which are found in Roman remains in England, is that they are but a little thicker than an ordinary tile, and longer and wider, than ours. Bricks were little used during the medieval period, although it is to this time that we over the interduction of glased bricks for ornamental work. over the introduction of glassed bricks for ornamentus work. For the less 300 years bricks have been extensively used in England, particularly in districts where clay is plentiful, and it is difficult and expensive to produre stone. There are many different kinds of brioks, which may be divided into three classes, as follows:—I. Bricks used for walling; Z. Fire-bricks; and S. Chinkers, or Paving Bricks. There are two and 3. Chikers, or Paving Bricks. There are two methods of burning bricks for walling, and they are accordingly called "kiln-burnt bricks" or "clampboordingly called The latter bricks are the most com-They are made of course stiff clay, which requires sand to be mixed with it to allow it to be worked with facility. These bricks are burnt in clamps or stacks of 500,000 to 1,000,000 in number, with the fuel interspersed among them, that every brick may be tho-roughly exposed to the action of the fire. If the fire is too strong, it causes the bricks to fuse and run together, and form hard irregular masses, called clinkers; but if the fire is not strong enough, the bricks turn out to be soft, and therefore unfit for building purposes. About one-tenth of every clamp is lost by the unequal action of the fire and breakage. When the clamp is sufficiently baked, the bricks are divided into classes, known as "outters," fine close-grained bricks, canses, mown as "outlers," me close-grained bricks, rather sett, and better suited for work in which the bricks require cutting; "picked stocks," bricks of a uniform red tint; "paviours," hard bricks fit for paving; "common stocks," or ordinary bricks; "grizzles," or soft bricks; and "burrs." The bricks also wary in colour, according to the degree of heat to which are exposed. Kiin-baked bricks, also called tim bricks," are made of a finer clay, which con-"malm bricks," are made of a finer clay, which con-tains a considerable quantity of carbonate of lime; for which reason great care is taken to prevent the air getting to the bricks while they are baking, for this would cause the lime to pass into a caustic state; and, when exposed to the action of the atmosphere, it would absorb moisture, which would cause it to swell and burst the brick in pieces. These malms are slowly burst the brick in pieces. These mains are slowly burnt in kilus; they are better for ornamental purposes, being of a pretty buff colour, but they are not so durable as the common bricks. The bricks made of Saffolk clay, which contains a great proportion of carbonate of lime, are nearly white in colour. From 20,000 to 30,000 are taked at once. The best mains come from Erith, in Kent, and Ware, in Hertfordshire. Fire-bricks are made of clay containing a considerable quantity of silicate of alumina, and as free as possible from line, in any form, or iron. The clay is carefully prepared, and the bricks are exposed to an intense heat in kilos, as they are required for building up furnaces, and other purposes, for which it is necessary that they should be able to with and the action of fire. The best fire-bricks are made at Stourbridge, Newcastle, and Edinburgh. Paving bricks are principe, Newcounte, and Edinburgh. Taving bricks are nuite of clay which contains a great amount of silica, that fuses when the bricks are burnt, and causes them to become very hard. Good paving bricks are made at Birmingham and Uppingham, but the best are brought from the Netherlands, made from the mud of the Yssel, and known as Dutch clinkers. Bricks were The I seet, and known as Dutch clinkers. Bricks were originally subject to a tax, which was first imposed in 1781, at the rate of 2s. 0d, per thousand, and increased by degrees to 5s. 10d. Glazed and polished bricks paid dairs at the rate of 12s. 10d, per thousand for those of ordinary mass, and 21. 4s. 2d. for any ones. The duty was sent and in 1850. Batt tracks are made at and acoust stringerwater, of the same of the river Purret, and that a restaurable forms a defined they are monifed into a rectangular form and dried; they are

metal-work. - Red. English Cyclopedia - Arte and

Sciences.

BRICK MARING.—To render the city ill for making bricks of a good quality, it is necessary that it should be dug in the autumn and expected to the air in small heaps, sometimes called "curfs," that the action of the rein and frosts of winter may ripen the clay, rendering it what the workmen call "mellow," and causing it to become more tenacious and plastic after it ting it to become more tensions and plastic after it has undergone the process of knowling. Sand or ashes must be mixed with the clay before knewling, which has the effect of making the bricks stronger, and more durable; the mixture is then worked or kneeded in what is called the "pug-mill," a great improvement what is called the "pug-mill," a great improvement on the old system, by which the clay was knowled by means of the workmen or cattle trampling on it, in a manner similar to the plan adopted for pressing grapes in wine countries, or threshing corn by oran in the East. The pug-mill is a large cylinder, with many arms projecting from the inner side towards the centre, up which a shall passes, from which other arms project, passing between those that are fastened to the sides of the cylinder. These arms, or knives, as they are technically called, are fitted to the cylinder and shaft in such a manner that the clay may be pressed from top to bottom of the machine in a spiral direction by the revolution of the shaft; the material is thrown in at the top, and comes out at the bottom in a state per-fectly fit for the moulder's uso. Formerly, the clay thus kneuded was taken to the moulder in lumps, who fashioned them into the required form by the aid of a wooden box of the proper size, into which, when sprinkled with sand to prevent adhesion, the clay was pressed, and then shaken out, in the shape of a bridge on a board, which sometimes had a projecting piece fastened to it to make a depression in the brick into which the mortar might enter, and so bind the brick-work more closely together. At the present time, however, the operations of keending and moulding are combined, and effected by the same machine. After combined, and elected by the back mast he pig-mill, the clay is discharged into a box, from which it is present by the action of a shaft rising and falling vertically into a mould of the required size; the mouldingframe then slides over an opening in the board which forms the bottom of the mould when under the shaft that fills it, and the brick is pressed out by the descending action of another shaft on a board placed to receive it, from which it is removed by a boy whose duty it is to watch the machine. The bricks are then piled up in such a manner as to leave room for the passage of the air between them, and allowed to dry; they are afterwards removed to a kin for baking, or hardened by burning in stacks with fuel thrown between the successive layers of bricks. The above method of moking bricks by machinery is that introduced by Mesers, Cook and Cunningham about 1840, whose machines will turn out about 1,800 bricks an hour. There are, however, many about 1,500 erics an nour. There are, nowers, many other machines, differing slightly in principle of action from that which has been described, and tarmore complicated in construction; among which may be manned that of Mesers, Heaton, of Birmingham, in which the bricks are made in metal moulds revolving on a wheel, and pass through successive stages of formation during the revolution, until the brick comes from the mould perfectly formed and ready for removal; that of M. Terrason, in which the clay is pressed into long troughs of the width and theichness of a brick, and cut, when discharged from the troughs, into pieces of the regulsite length by a frame, across which wires are stretched suc leaght by a rame, across which were are arrectaged, to effect the cutting process, after which the bricks are conveyed by machinery acting on an inclined plane to any desired distance, for stacking, drying, and burning; and that of Mr. Jones, in which the clay is mixed. to a stiffer consistency, and therefore requires less rine for drving when formed into bricks. There is time for drying when formed into bricks. There is also a method, originated by Mr. Prosser, of turning out bricks almost dry from metal moulds, in which the clay has been subjected to very great pressure. Ber. English Cyclopædiu. Arts and Sciences.

BRICKWORK .- The thickness of walls of houses built or brick is regulated by the length of the brick, which is nine inches; walls, therefore, are spoken of as being is nine inches; walls, therefore, are spoken of as being half a brick, a brick, a brick and a half, &c., in thickness. In houses, generally, the outer wells are from

### Brickwork

ens brick to two in thickness, and the partition walls only half a brick thick. In public buildings, and walls in which great strength is rangifired, they are sometimes more than four bricks thick; but it is considered good substantial work when they are made of the thickness of three bricks well bonded together. Garden walls are half a brick or a brick in thickness; they are often strengthened by the addition of piers, about 10 or 12 feet apart, and about 18 inches in width, projecting at inches or 0 inches from the face of the wall; they are fluished with a coping of bricks laid on the side. In loose soil it is necessary to form a foundation for the wall by filling a deep trench with atone and rabbish, which is often cemented together with concrete. In bricklering, care must be taken that the bricks are well-bonded, that its, that the successive layers of bricks mysig, once must be seen that it is the successive layers of bricks may be so placed that no joint in any layer shall come mendiately over snother joint in the layer below it. Bach layer of bricks is called "a course." When bricks are laid with the side facing outwards, and lengthwise in the course, they are termed stretchers, and the course is called a stretching-course; but when the end appears in the face of the wall, they are called headers, and the course a heading-course. four principal methods of bonding bricks together, called English bond, Flemish bond, herring bond, and English bond consists of stretching garden bond. courses and heading-courses alternately; Flomish bond courses and resulting courses afternately; riemian nond, in laying a stretcher and header alternately in each course. Herring bond is used for the core of thick walls, alternate courses of bricks being laid between the outer and inner laces diagonally, at an angle of 45° to the face, each course being also laid in an opposite divection to that on which it rest: this leaves site direction to that on which it rests; this leaves triangular aps ses between the core and the face of the is supposed to give strength to walls the but it faces of which are built on the principle of the Flemish bond; hoop iron is sometimes laid between the courses of Flemish bond to give strength to the wall and tie it together. Garden bond consists of three stretchers and a header in every course : it is only used for walls of the thickness of one brick. Arches of brickwork are always constructed on wooden centring, which is afterwards removed. The formation of groined work, or the intersection of arches in a vault, with bricks, is difrme incersection or arches in a vaor, with threes, is dif-ficult, as in this, as well as in every other kind of arch, elliptical, segmental, and straight, except those that are senticircular in form, every brick has to be bevelled at a different angle to it the curve of the arch. The brickle are cut by the bricklawer to the required shape by the brick-are, and are afterwards brought to an even surface by rubbing on the "banker," or rubbing-table. Nest workmanship is required in shaping and putting together the bricks in any kind of arch. That the settlement of brick walls may be the same in all parts, they should be built up to the same level in all parts at once. Mortar, made of lime and sand, is used for comenting brickwork together; twice as much sand as lime is the proportion generally used in the composition of mortar, rather more being required for mortar made with stone-lime than for that made with chalk-lime. To give a finish to brickwork, it is sometimes pointed with blue or white cement or plaster. When the pointmind one or wine cement or plaster. When the pointing is on a level with the surface of the brickwork, it is called "flat-joint pointing;" when it is raised above it, it is termed "tuck-joint pointing;" the former is generally done in blue mortar, and the latter by adding a raised line of white cement on the surface of the blue morter that is first inserted between the courses. a brick and a helf thick; this will be found to be calculated to be about 15 tons, constituted 4,500 bricks, swighing on an average 10 tons, and 5 tons of mortas, composed of 80 cubic feet of and and half that quantity of chalk lime. Many fine specimens of brickwerk are to be seen in continental cities; the most curious is that in the Marien Kirche in Brauthe most curious is that in the Marien Kirche in Brau-deaburg, in North Prussia. In and near London, Rampton Court, St. James's Square, the Thames Tunnel, the fine warehouses in New Cannon Street, near St. Paul's, and the viaduets of the various railways, may be mentioned as the best examples of Buglish brickwork; and the enormous factory chim- at marriages is a custom of remote antiquity. In the neys in Lancashire, Yorkshire, and about Glasgow, north of England a custom formerly prevailed of the

## Bride and Bridegroom

some of which tower upwards to the height of 460 hat.

—Est Emplish Cynlopedia.—Arts and Sciences; Fichtelson's Dictionary of Architecture.

BEIDS AND BEIDSEROOM, bride, bride'-groom.—
Various derivations have been given of these words.

According to Tooke, bride is the past particulate of the Ang. Sex. verb bredan, to nourish or cherich, and groom the past participle of gyman, to take care of, guard, attend; so that the bride is a woman nourished and of rished, and the bridegroom is one by whom she is at-tended, served, and protected. They denote respectively a newly-married woman and man, married on the first day of their wedded life. The end on the first day of their wedded life. The enjoyment of these titles being necessarily brief, they have always being associated with numerous ceremonies. Among the ancient Greeks the bride was usually conducted to her future home in a chariot drawn by mules, with her husband on one side and his most intimate friend on husband on one side and his most intimate itself on the other, the hridal party forming a procession with torches and singing. On reaching the end of their journey, the axie-tree of the chariot was broken, to signify that she was to remain there. The marriage feast was then celebrated, after which the bride was conducted by the bridegroom to her spartment; where, by the laws of Solon, they were required to est a quince together, while the printal anima, or bridal-gong, was sung by the young men and maids outside. The day after the marriage presents were made to the newly-married couple by their friends. Among the Romans the bride was conducted to the house of the bridegroom by a procession resembling that among the Greeks, bearing in her hands the emblems of diligence,—a distaff and a spindle with wool. She was lifted over the threshold by two married men, and received by the bridgeroom within with fire and water, symbols of partification. The keys of the house were then prese to her, and the ceremonies concluded with a feast, after which she was conducted to her apartment by matrons who had only had one husband, and ministress matricis who had buy had one had the had the hight, and friends sang epithalamia without during the night. Usually there was a pretended seizare and carrying off of the bride from her parents, in memory of the rape of the Sabines. Formerly it was the custom to drink wine in the church after the cup had been first blessed, by the priest; and among the Jews wine-drinking at marriage is still universal, the glass being broken after the bride and bridegroom have partaken of it, to re mind them of the perishableness of all carthly things. The bridal kiss is of unknown antiquity, and is enjoined as an essential part of the marriage ceremony in the old missals long before the "Common Prayer-Book." It was always done in the church, and, at one time liberty to kiss the bride was among the perquisites of the priest. In account times wheat was sprinkled upon the head of the bride, indicative of a hope that the newly-married pair may always be supplied with an abundance of the good things of this life; but in later times the wheat has taken the more presentable shape of a cake. In England and Scotland the cake was formerly broken over the head of the bride, but it now takes the form of a highly-ornamented piece of confectionery. It consists of a rich cake as a basis, surmounted by a light superstructure of various devices, the whole being covered with a preparation of white subors augar. Bride furours are small knots of white ribbons pinned to the breasts of all who are in attendance at weddings, a knot, among the ancient northern nations, being a symbol of love, faith, and friendship : formerly the ribbons were of various colours. The use of bride maids at weddings appears as old as the time of the Anglo-Saxons, among whom, as Strutt informs us, "the bride was led by a matron, who was called the bride's woman, followed by a company of young maidens, who were called the bride's maids." In later times it was among the offices of the bridemaids to lead the bride-groom to church, as it was that of the bridegroom's men to conduct the bride thither. Part of the duties of the bridemaids consisted in dressing and undressing the bride; and the bridegroom's men performed the same offices to the bridegroom. Bridemaids, as mere ceremonious attendants at marriages, are still in use in England, and the bridegroom is usually attended only by one confidential friend. The giving of glores only by one confidential friend. The giving of gloves at marriages is a custom of remore antiquity. In the

young men present at a wedding, immediately after the ceremony, striving who should first plack off the bride's garters from her legs, and whoever were the rictors on this occasion worse them about the church is triumph. Bride size, aride bath, and bride rizke, are nearly synonymous terms, and all derived from the castom of the bride's aciling ale on the wedding day, for which she received, by way of contribution, whatever price the friends assembled chose to pay for it; the expenses of a wedding fear were in this way discharged among the friends and relations of a couple who were not in circumstances to bear it. Somewhat of the against land was the penny wedding, which was of the same kind was the penny wedding, which was formerly not infrequent among the poorer classes of bootland, when the friends of the newly-married pair each contributed a certain sum to the expenses of the feast, and any one might be admitted to it on payment of a certain sum. Flinging the stocking was also among the customs generally observed on the marriage night m Kngland. It consisted in the young men taking the bride's stockings, and the young women those of the bridegroom, and each, sitting at the foot of the bed, threw a stocking over their heads, endeavouring to make it fall upon that of the bride or her spouse; and If the bridegroom's stockings, thrown by the young women, fall upon the bridegroom's head, or those of the bride upon her head, it was taken as a sign that they themselves would soon be married. The sack savy unconserves would soon be harried. The sace, posset, too, was also a custom that generally prevailed among our ancestors: it was a kind of caudle, made up of milk, wine, yolks of eggs, sugar, cinnamon, and nutureg, and had to be esten by the newly-married pair after boing put to bed. Among the numerous practical jokes that were not unfrequently put in force on such an occasion was the sewing up the bride in

But, since it must be done, dispatch and sowe Up in a sheet your bride."

Hesperides.

BRIDEWELL, bride'-well, denotes, generally, a house correction. The name is derived from St. Bride's of correction. The name is derived from St. Bride's Well, in Blackfriars, London, which was anciently much resorted to by pilgrims, and on the site of which an hospital was founded by Edward VI. in 1553. It was given over to the city of London to be used as a state of the city of London to be used as a of correction. workings for the poor, and a house of correction for the ide and vagrant. It afterwards came to be used as a place of punishment for criminals. As belonging to the city of London, it is under the control of the

lord mayor, and not under the sheriff.

Bridge, bridj (Sax. brigge; Ger. brücke).—A structure of wood, stone, or iron, thrown across a river, or any channel in which water flows, for the transit of sengers and goods from one side to the other, or over a railway, to carry a roadway above it at a higher level. Bridges thrown across a valley for the purpose of conveying water are called aqueducts (see Aqua-puct), and those for carrying a railway or roadway over a ralley are called viaducts (see VIADUCT). Different terms are given to bridges according to any difference in their construction or difference of purpose. They may be broadly classified as fixed or movable. They may be probaby classified as fixed or movable. Among the fixed bridges are the ordinary bridge, the suspension bridge, the tubular bridge, the frame bridge, the lattice bridge, and the skew bridge, a variety of the ordinary bridge, introduced by modern engineers to allow a railway to pass over a road or river at an angle otherwise than a right angle. or river at an angle otherwise than a right angle, without altering the direction of either, or placing the piers phlerwise than parallel to the direction of the stream (see Suspension, Tenulas, Frame, Latrice, Serw Bridge); and, among movable LATRICE, SERW BRIDGE); and, among movable bridges, are the floating bridge, flying bridge, draw-bridge, and swing-bridge. (See Ferry, Floating Bridge, Daawnsidge). Military bridges are of BRIDER, URAWRIDER: MINIST Propes are on an entirely different nature, and are noticed under another head. (See Brider, Ministrany.) The technical terms amployed in bridge-building with regard to the arch will be found under the general description of the arch was Acul; but it must be added, that the must see of masoury erected at either end of the bridge, which generally sustain the thrust of the whole series of anches, are called the abutments; those in the bed the arches soring, the piers: of the stream, from which the arches spring, the piers;

352

and the filling in between the top of the arches and th and the filling in between the top of the arches and the roadway, the spanfil. It may also be remarked that the term arch is applied to the structure of that form when made of stone, brick, or east iron; while, in bridges of wood and wronght iron; is in called the bay. The bridges of the ancients appear to have been claim-sily and unskilfully made of broad stones or planks reating on perpendicular piers, sithough they were that to construct efficient temperary bridges for the transportation of large bodies of troops ecross rivers and pieces of water of considerable breach, seevinged in the passage of the Hellespont by Zerres, 480 p.c. when he led across an immense army of Persians and auxiliary troops for the invasion of Greece. Bridges about Rome were made of wood, even sher the Clo Maxima, or great sewer of Rome, had been ancessed arched over. The famous wooden bridge that Horatius Cocles so bravely defended when Lars Possens menaced Rome, was made of wood; and it app that the earliest known bridge of stone over the Tiber, and, perhaps, the first stone bridge ever built, was the Pons Senatorius, now the Ponte Rotto, built by C. Flavius Scipio, 127 B.O.; but in later ages, the magnificent bridges and viaducts built under the Cassars in various parts of the empire, give the Roman people the credit of having introduced the art of bridge-building into Europe, and, indeed, show them to have been the originators of the art with respect to the application of the arch to such a purpose, although the Chinese claim to have constructed arched bridges at a far earlier period, which is a matter of doubt, owing to the un-certainty that exists with regard to the truth of their chronological records. Among the numerous bridges built by the Romans may be mentioned that which was erected by Trajan over the Danube, consisting of twenty semicircular arches, with a span of 180 feet, springing from abutments 64 feet wide and 85 feet thick, at a beight of 46 feet above the surface of the giver. This height of 46 feet above the surface of the river. bridge no longer exists, having been destroyed by Hadrian to prevent the Dacians from using it as a means of making incursions on the Roman territory. With the decime of the Roman empire, bridge-building was neglected until the time of Charlemagne, who mast tuted a society known as the order of the Frees du Pont, or Brethren of the Bridge, whose duty it was to see to the erection and repairs of bridges and the establishment of ferries in various parts of France and Germany, among whose earliest works are reckoned the bridge of Avignor, over the Rhone, and that of Ratisbon. A fresh impulse was given to bridge-building in France by the establishment of the corps of the Ponts et Chausses, about 1720, who built the Pont de la Concorde at Paris, and many other notable bridges at Blois, Cricans, and Saumur, and in various parts of the country. In England, the first stone bridge built the country. In England, the first stone bridge built was that of Bow, near Stratford, in 1037, followed by old London Bridge, in 1176. Old Westminster Bridge completed in 1750, was once considered the finest in the world; but it is surpassed by the new structure which has been erected in its place. In 1775, Mr. Pritchard, of Shrewsbury, commenced the construction of cast-iron bridges by putting up one at Coal-brookdale; and this example of the adaptation of iron-work to the formation of bridges was followed by Wilson, of Sunderland, and Telford. Since the commencement of the present century, the art of bridge-building has rapidly developed itself under the requirements produced by the introduction of railways and the increased facilities of locomotion, and the result is shown in the new forms of the suspension bridge, the wrought-iron girder bridge, the lattice bridge, and the tabular bridge, as exemplified in the Menai and Cheisea. suspension bridges, the High Level Bridge at Mew-custle, and the Britanuis, Conway, and Selfash tutulage bridges, the last named of which is also known as the Albert Bridge. The bridge over the Delaware at Trenton, in America, and the Niagara suspension bridge are also magnificent bridges, and the Victoria Bridge over the St. Lawrence, in Canada, is the largest tutular bridge in the world. There are many noming tubular bridge in the world. There are many points of great importance to be considered before designing and commencing the construction of a bridge across any piece of water, and the form and nature of the bridge should depend mainly on the results derived from a careful inquiry into these points. For instance,

a slow, singgish stream, flowing through a dist country at the rate of a lettle mane than a grantee of a mile year hour, would not require a budge with high mears and letty arches with a broad grant as grant against the sudden rest of a least stage, which would carry down large trees and accompanies wasses of differed, that might stick fast under or against the bridge and prove the means of the destruction; or the other hand, a bridge of this sometraphon would be absolutely secsion; for a rated river destring its supply from a waterabed of many miles as superficial extent, and flowing between steen banks. The pounts, then, to be first considered, are the extent of waterway that is necessary, and she form that the bridge should take with reference to the character of the stream. The extent of waterway depends on the superficial extent, shape, and gradges formation of the country that field the river over which the withrough lands of a posque or sandy nature, in which the volume hand or a posque or sandy nature, in which the volume a clow, alugush stream, flowing through a flat country lands of a possess or sandy nature, in which the volume of water passing under is subject to little variation, require buy little waterway, while those which run through land which is steep and hilly in character, sarough same where is accept and they in character, and costains underlying strate of granite, innestone, and slate, or heds of thick clay and loam, which will not absorb any surplus till of ram, require a waterway of cognidarable actent. Thus under the former conditions, the waterway of a bridge would not require a greater depth than one not for every square mile of ground that supplies the river that passes under it, while in sountries where the ground is very steep and mountainous, the strate non absorbent, and the rains beavy and frequent, producing sudden floods, a water-way equivalent to four feet and a halt per square mile of watershed strequeste It must be remembered that these dimensions form the opposite extremes of a scale, or the greatest and least depth of waterway re scale, or the greatest and least depth of waternay required per square mile, a c rding to circumstances and that, aithough a sufficient amount of waternay would be secured in the case where the depth allowed is of such narrow limits, tradges are solden built, symmin flat country a such as Holland, with an small ay allowance for depth, or in mountainous and builty districts with so much Next in importance to the waterway is the character of the stream, its average velocity and liability to sudden increase must be ascertained before determining the number and strength of the piers to be placed in the bed of the river of the piers to be olaced in the hed of the river. The piers will naturally tond to diminish the breasth of claimed through which the waters pies, causing an accumulation of the water in mediately above the bridge, and, in consequence of the au increase of velocity below. The fewer the number of piers the briter in all rases, particularly in briging rivers which flow at the rate of three mits per hour and upwards as is the case with rivers that run over shingly and rocky strains. The required amount of waterway and the objective of the strain. the rigranter of the stream having been ascritained, the purpose for which the bridge is intended to serve. the weight the piers an larches will have to bear and the weight the piers and arther will live to being and the taken into account as the form and method of construction to be adopted in building these parts of the bridge mainly depend on these points. It is an invariable rule that the piers should rise at least as high, or a little higher, than the level attained by the water of the triver when swellen his a hieray flood rishing from the uplands, this will effectually prevent the water from rising at any time as high as the keystone of the arrely, which will mater ally affect the stability of the bridge. They must also be constructed of a sociating in proportion to the time of the current, and the weight they must ustain in a vertical direction, as they are not intended to support the lateral thrust of the arches, which is generally directed, in the case of bridges of great lend the through the entire arrives against the missine shutments at the ades After securing proper foundations for the abutments and places, which often have to be made of masses of a sidd massagey or concrete (see Concrete, Corpertuly, within elements in low the bed of the preve, owing to the nature of the soil and the geological formation undernessin, the nature mu t be taken into account as the form and method of

These weights will m resolve a destructive pressure on the elec-sless; and it must be the care of the engine trust them of sufficient size and strength: Street them of sufficient size and strength to be a successive should apply them at every soint, and insure the steining of the bridge. It collections weight of the place of and per equate foot a made for ordinary bridges, 800 lbs. For railway bridges; the weights of the aparts are found by calculations based on the accrement of the same With regard to the severted by the strength of the current against the mean velocity of the water and the superficult the mean velocity of the water and the superficult and the protected against the rash of the owners should be protected against the rash of the owners. of the end of the pier exposed to its action. The piers should be protected against the rush of the emrical by the addition of what are called cuprature, which are pieces of masonry the horizontal section of which is an equilateral triangle, projecting from the andle of the piers in the form and exercising the functions of a wedge, which divide the water in its compa, and thereby materially it seen the momentum with which it comes against them In non-tidal rivers, out need only be placed on that side of the give which is opposed to the direction of the wreem, but in side in the total control of the wreem, but in side in the total control of the wreem, but in side in the repeat to the form of the arch to be employed, an alliquisid of segmental arch is most degant in appearance, particularly cularly a segmental arch, which is one with of the circumference of a circle, subtending an angle of 50°, in which the versed sine is exactly equal to ene-fourth of the span In segmental arcnes the lateral thruit on of the span In segmental arenes the lateral taries of the abunents is greater than in any other form; but as the vousions forming an arch on this construction can all be cut from the same mould, as well as those of the same incular arch, there can be erected at less explains than an elliptical arch. But when the semicircular form is used, unless the banks of the river by warrenest that the approaches to the bridge are such as the contract the deduction. warrant its adoption, the roadway must necessaril kept at a considerable height above the level of water, particularly if the water in the river be subject to great increase after heavy rains, as the pars must be rai cd above the level of the flood-line. The following bridges in various parts of Great Britain and Ireland afford good examples of such construct Ireland afford good examples of such constructions with elliptical, semicircular, and segmental archiva. I lipitual — London Bridge, Blackfeiner Bridge, Waterloo Bridge and Limerick Bridge Semicircular in Strekport Bridge and Limerick Bridge Semicircular in Strekport Bridge and True viaduots. Segmental — Cherter, Coldstream, Glasgow, Towkesbury, and Vauxball Lindges, with old Rootster Bridge, and the Vale Royal Viaduot the arches of the two structures last named are segments subtending an angle of 1972. A greater extent of stang can be obstructures as a lamed are segments suctending an angle of 60° A greater extent of span can be obtained in suspension and tub ilar bridges, and those constructed with east run griders, than in bridges of masonry or brickwork. The arch of the bridge at Chester which is 20) feet a span, with a ruse arresped sine of \$2 feet, is perhaps the largest built of stone in this country. In building bridges of stone or brighwork the engineer has to exercise great care in the construction of the centre or wooden framing on which the aich is built (See Critzine) The principal requirements for a centre are that it should be well braced together with cross tunbers, to avoid any dis-placement of the truses laterally, that it should be exactly summar in outline to the curve proposed for the intra los, or line formed by the lower ends of the vous-soirs of which the arch is composed, allowance being sours of which the arch is composed, allowance being made for the compression of the wooden frame under the heavy weight that is to be piled upon it, and that it should be supported in such a manner that it can be easily removed without injury to the arch at can be easily removed without injury to the arch as soon as the masonry is completed. The common plan is to support the centring on we iges, which are driven out when the stemeowerk is function; but the French have adouted a plan of waiting it on pandhear, which was he adopted a plan of resting it on sandbags, which can be easily removed without causing any ribrasion in the the fresh masonry, which must be produced, and often with serious migray to the work, where the wedges are struck out by blows of a handner. Wooden bridges are often used instead of stone 12 countries such as ne tow the use of the river, owing to the nature of the riven masonry, which must be produced, and other soil and the geological formation underweith, the next with serious unjury to the wolk, where the usedges are thing will be to calculate the weight of the passing load, atruck out by blows of a handler. Wooden bridges the weight of the superincumhent mass between the arc often used instead of stone in contrives such as crowns of the archae and the readway, and the weight of. America, where timber is cheap, but they are liable

as simple as possible in to throw the pressure foundations or supports y should be made with due e and proper halance of the pressure which they are exposed (See Cas-) Iron bridges are of various kinds, a already stated, suspension, lattice, Bridges of metal are liable to contraction under the influence of heat at allowance can always be made for this in adifferent parts of which they are composed in the support to throw a straight bridge over a without having recourse to the support of without having recourse to the support of parsecularly in the metrop his and its sur of subarbs, pirders of cast hou may be used by space to be bridged over does not exceed bots when it is more than the to the when it is more than this recourse should to wrought-iron girdeis. structed for the defence of any town, or thrown up instily to secure the retreat of an army across a river, and to enable a small body of defenders to hold the enemy in check until the retreat has been safely effected, and means have been taken to destroy the bridge by which the passage has been made. The common form of a bridge-head is a breastwork open in the rear, offering a salient angle to the attacking force; sometimes it is formed by bastions regularly connected by cortains, or by a series of redoubts. The most favourable position for a bridge-head, or tele-du-post, as it is generally called, is when the bridge which it is intended to defend is situate at a re-entering bend of the river, by where the river forms an are, having the chord which subtends it on the same eide as the bridge-head.

There is no where the river forms an arc, having the chord this subtends it on the same side as the bridge-head. The first monastery of the order was created at Wadden, and the process a river, are of various kinds. The best are those species as five, are of various kinds. Before Halp, in Mil., a fortification intended for the defence of a bridge, built either to secure the bridge from the sudden attack of an enemy, and then forming an essential portion of the regular works conforming an essential portion of the regular works consisting of a couble row of piles, to which spars are formed of planks lashed to a frame of timber or trees felled on the spot. v. The pile-and-spar bridge, consisting of a double row of piles, to which spars are lashed that support timbers laid across them. There are also what are termed flying-bridges. The swing flying-bridge consists of one or more boats attached Hyling-Dringe consists of one or more noise assuments to a rope, which is fastened at the other end to a buoy in the middle of the river, or to a take in one of its banks: the boat is carried across the atream by the action of the current, and hauled back to the shore from which it started by means of another rope. The trail flying bridge is a boat or raft attached by rings to a guide-rope fixed neross the stream to stakes on either bank, and drawn backwards and forwards.

BRIDGETINES, BRIGITTINS, or BIRGITINES, bridge-e-time.—A religious order, founded by St. Bridget of Sweden, in 1344, and afterwards confirmed by Urban V.

feeted in the Creation." It was judged preferable, in place of giving the whole sum to one man for one case, to divide it into eight equal parts, to be given to eight different persons for as many distinct treatises on subjects connected with the original theme. The several subjects, with the distinguished authors selected to write upon them, were as follows:—1. The Adaptation of External Nature to the Moral and Intellectual Constitution of External Nature to the Moral and Intellectual ation of External Nature to the alloyal and intellectual Constitution of Man, by T. Chalmors, D.D.; 2. Chemistry, Meteorology, and the Function of Digestion, considered with reference to Natural Theology, by William Prout, M.D.; 3. On the History, Habits, and Instincts of Animals, by the Rev. William Kirby; 4. On Geology and Mineralogy, by the Rev. William Buckland, D.D.; 5. The Hand, its Mechanism and Vital Endowments, as evincing Design, by Sir Charles Bell; 6. The Adaptation of External Nature to the Physical Condition of Man, by John Kidd, M.D.; 7.
Astronomy and General Physics, considered with reference to Natural Theology, by the Rev. William Whewell; 8. Animal and Vegetable Physiology, considered with reference to Natural Theology, by P. M. Forst M.D. All of these south phase ways here. Roget, M.D. All of these works have since been re-printed by Bohn in his Scientific Library.

BRIEF, breef (Lat. brevis, short), in Law, is a concise statement of the facts in a cause before a court, and of

the evidence in support thereof, with observations of the attorney or solicitor engaged for the party on whose behalf it is prepared, and references to decided cases affecting any legal points in dispute. It forms the in-structions to counsel who has the management of the cause on behalf of the client, and it should, as far as possible, develop all that can be collected in favour of the opponent, so as to give an opportunity to counsel to anticipate what may be advanced to the prejudice of his client. After delivery of the brief, it is usual to have a consultation with counsel, who advises with his junior (if one be retained) and the attorney or solicitor, and determines on the course to be taken before a jury

BRIEF, in the English Prayer-book, denotes the sovereign letters patent authorizing a collection for a charitable purpose. They are directed to be read among the notices after the Nicene Creed. — Ref. Hook's Church Dictionary.

BRIEF, PAPAL, a pontifical letter dispatched from the court of Rome to princes or other high personages. A papal brief differs from a papal buil in heing less ursple, and in being always written upon paper scaled with red war, with the pope's private seal, the fisherman's ring; hence it concludes with Datum Roma, sub annulo piscatoris (given at Rome, under the ring of the fisherman). The papel bull, on the other hand, is always written upon the rough side of a sheet of parchment, and in ancient Gothic characters. (See Bull, Paral.) The papal brief is issued to decide affairs of inferior importance to those adjudicated

upon by the papal bull.

BRIG OF BRIGANTINE, brig (Fr.), in Mar., a name penerally applied to a square-rigged merchantman with two musts, though mariners of different countries

andiv ìŧ some peculiar vessel in their

length, and fusiened to a vard which hangs parallel to the deck; but in a brig, the foremost edge of the mainsail is fastened in dif-ferent places to hoops, which evoircle the mainmast, and able up and down it as the sail is hoisted or 357

towored: It is extended by a geff above and a below. This term is also used to designate a light, flat, open ressel, which can be propelled by salls or ours, used either for fighting or giving. Baleans, brig-aid (Fr.), in Mil., a term apple body consisting of two or more regiments or batter two brigades thus composed forming a disrision army sent into the field. When a number of regiment and the composed common and the state composed are stationed in any camp, such as the composite of the compo are stationed in any camp, such as the comp at Al shot or the Curragh, they are generally grouped brigades. A brigade varies considerably in pure strength, as it may include from two to us battall of infantry, or the same number of squadross cavalry. A brigade of artillery consists of two or the batteries, either of foot or lorse artillery, and eight men form what is called a brigade of Suppers and Miners. The term Household Brigade is sopiled to the household troops, consisting of the Horse-guards, Life-guards, and Foot-guards.

BEIGADE-MAJOR, an officer who is attached to a brigade to perform duties similar to those of the adjutant of a regiment, and acts as an aide de camp to the brigadier-general. He must be a captain or sub-altern officer, and is generally selected from among the captains of the regiments forming the brigade.

captains of the regiments forming use or agreements. BeligaDish Carnerat, briga-deer, the mains given, in Mil., to the officer selected to take the command of a brigade. The post is generally given to one of the colonels commanding the regiments of which the brigade is composed. He holds temporary rank between a colonel and major-general.

BRIGAND. (See BANDIT.)

BRIGANDINE, brig'-an-deen (Fr. brigantin), a coast of mail composed of small scales or pieces of metal sewn upon a closely-fitting tunic of linen or leather, and sometimes covered externally with the same material. It seems to have resembled the tegulated armour of the time of Stephen.

BRIGHT'S DISEASE, OF GRANULAR DISEASE OF THE KIDNEYS, brites, is a particular disease of the kidneys, named after the late Dr. Bright, who first pointed out its nature and character. It consists in a degeneration of the tissues of the kidneys into fat, by which their secreting powers are impaired, and the urea is not sufficiently separated from the blood the urea is not sufficiently separated from the cooca. The distinguishing characteristic of this disease is the existence of albumen in the urine, which, though not invariably, is almost always present, and is readily detected by its coagulating on the application of heat. Healthy urine contains no albumen, which is the great agent in nutrition. It is obtained here at the expense of the serum of the blood, and no disease so plosely approaches hiemorrhage in its power of impoverishing the blood and exhausting its red particles. Hence arises that waxy and leucophlegmatic aspect which so strongly characterizes this complaint. Patients labouratrongly characterizes this complaint. Fatients incouring under this disease are liable to inflammatory and congestive states of other important organs; and heave coms, convulsions, and apoplexy may occur during its progress. The heart, too, may become implicated, and dropsy almost always occurs, sooner or later. This dropsy almost always occurs, sooner or later. This disease may be occasioned by severe cold, repressed perspiration, or immoderate use of ardent spirits, and t not uncommonly follows scarlet fever. In the treatment, the secretions of the skin are to be encouraged by the use of warm baths and disphereties, and the dropsical tendency is to be counteracted, as far as possible, by purratives and directics. Local bleeding pessible, by purgatives and diureties. Local bleeding is frequently beneficial, but general bleeding is to be avoided, from the exhausting tendency of the disease.

BRILL, or PRARL, bril (Pleuronectes thousands); a fish resembling the turbot in shape, but inferior to it both as regards size and quality. The London market is resembling the turbot in shape, Due much market is as regards size and quality. The London market is chiefly supplied from the southern coast of England, where the brill is very plertriful. The brill is distinguished from the turbot by the perfect amoothness of its akin, which is covered with small sosies, and marked with yellowish or rufous spots. As is the case with the turbot, the lateral line first describes as are over the pectoral fine, and then rune straight to the tail. The brill very seldom attain an equal weight with the turbot, rarely going beyond 7 th. It is found both in turbot, rarely going beyond 7 the. The sole and turbot, rarely going beyond 7 ib. It is found both in deep water, as well as in sandy bays. The sale and the flounder belong to the same lamily as the brill.

BRILLIANT, brill-yant (Er. brillant), a name given

to the diamond when cut is the following manner:

The principal face, which is called the table, is surrounded by a fringe composed of a number of facets,
which is all that is raible above the besel when set.

The proportion for the depth should be half the breadth
of the stone, terminated with a small face parallel to
the table, and connected with the surface by elongated The Media, and commissed with the wind to common na-facets. As the octahedron is the most formon na-tural form of the stone, and the brilliant cut is by far the most advantageous in point of effect, besides being the most advantageous form that can be adopted, it is

the most economical form that can be adopted, it is generally preferred. (See Sulvuus.) Brissroofs. (See Sulvuus.) Cicl, when it is formed by dissolving salt in water. Brine-springs are fountains which flow with salt water instead of fresh. There are several of them in dif-

ferent parts of England.

Harring, bris sels (Sax. bristle), are the long, stiff, course hairs taken from the hog, and are principally used in brosh-making. They are mostly imported from Russia and Poland to the amount of 3,000,000 lbs. weight annually. They are separated into different qualities and colours by children, the whitest being technically termed lilies, the rest black, yellow, or

grey, as the case may be.

BRISTOL DIAMONDS, bris'-tol, small brilliant hexagonal crystals of white quartz, found in the limestone

at Chifton, near Bristol.

Brisure, bre-zoor (Fr. briser, to break), in Mil., an expression applied to any part of a parapet or ramart which is constructed in a direction different to that part of the fortification of which it forms a contimona portion. In field works the term brisare is applied to the faces of a star fort, or those of any line of defensive works consisting of a series of re-entering and selient angles.

BRITANNIA METAL, brit-tan'-ya, an alloy of tin, lead, entimony, and brass, in very varying proportions, some makers using equal parts of these metals, while others use an excess of tin amounting to 74 per cent; of the whole. Britannia metal is much used for

spons, feapots, &c. &c., on account of the case with which it may be worked and polished.

BRIANNIA TURULAR BRIDGE, a bridge built by the directors of the Chester and Holyhead railway. ever the Mensi Strait, to connect the island of Angle sey by railway with the mainland, and admit of the transit of passengers and mails to Holyhead, en route to Ireland, without interruption. It was designed by Mr. Robert Stephenson and Mr. Fairbairn, the celebrated engineers (see vol. I. of this work), in 1845, and is remarkable for being the first tubular bridge ever erected. Four important requisites have been satisfied in the construction of this and other bridges on the same principle,—strength, lightness, a span of considerable extent without the support of arches, and nonrathe extent without the support of stenes, and non-interference with the navigation of the waters over which they are thrown. (See Tublian Building The building was commenced in 1836, and the structure completely limited in 1850, one line of tubes being thrown open for traffic in the month of March in that car, and the other in August. The entire length of year, and the other in August. The entire length of the bridge is about 1,840 feet; but the tubes extend to a distance of about 1,512 feet from end to end. The bridge coreists of a double line of tubes, each formed of four state pieces of tubing, supported on three tories of the six pieces of tubing, supported on three tories of the six emasury and two abutments, one on the Anglesey side, the other on the Cacraryon side of the struct. The principal or central support, called the Britannia Toner, is built on a rock which rises above the level of the water in the middle of the strait; it is altogether 191 feet us height, the height of the masoury on which the tube rests being 104 feet above high water-mark. The supports between the central tower and the abutments are built near the shore on other side, and are about 173 feet in beight. The span between the Britannia Tower and the tower on the Carmarvon side is 459 feet 3 inches, and between this tower and the abutment 229 feet; while the span between the Britannia Tower and the tower on the Anglescy side is 453 feet Sinches, and between this tower and the shut-ment 230 feet. The tubes stretching from tower to

tower are twelve feet longer than the span at either end, and considerably more at the abstances; ther rest on bed-plates, which move on rollers and balls of cast iron, to admit of the expansion and contraction of the metal of which the tubes are composed, under the influence of heat and cold. The tube is higher in the influence of heat and cold. The tube is higher in the centre than at either end, the top being in the focus of a parabolic curve; the height externally in the middle is 30 feet, and at either end 22 feet 9 inches; internally is at feet, and at enter end 22 rect threese; undersay, it is 26 feet high in the centre, and 18 feet binches at the extremities, the thickness of the walls being 2 feet; the width of the interior of the tubes is 13 feet 8 inches, and is the same throughout. The iron of which the tubes are made, exclusive of more than swo millions of rivets used to fasten the plates and girders together, weighs 10,550 tons, of which 9,860 are wrought iron; helps and rails. There are nearly 1,500,000 cubic feet of masonry in the towers and abutments. The long tubes, spanning the water from tower to tower, were built on shore, and floated off on pontoons; they were then gradually and successfully raised to their p position by enormous hydraulic pressure, an achieve-ment which is regarded as one of the most remarkable engineering operations of modern times. The entire cost of the structure was about £600,000.

BRITISH ARMY, (See ABMY.)
REITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, is an association of men of science, which meets annually in one of the larger towns of the United Kingdom, and has for its object "to give a stronger impulse and a more systematic direction to scientific inquiry,—to promote the intercourse of those who cultivate science in different parts of the British empire with one another and with foreign philoso-phers,—to obtain a more general attention to the objects of science, and a removal of any disadvantages of a public kind which impede its progress." It is divided into several sections, each of which has a president, vice-presidents, secretaries, and council. The sections are as follows:—A. Mathematics and Physics; B. Chemistry and Mineralogy, including their applications Chemistry and Mineralogy, including their applications to Agriculture and the Arts; C. Geology: D. Zoology and Botany, including Physiology; sub-section D. Physiological Science; E. Geography and Ethnology; F. Economic Science and Statistics; G. Meelasnical Science. Life members pay, on admission, £10; annual subscribers pay £2 for first year, and £1 every subsequent year; and associates pay £1 for admission to the meetings, &c. Life members and annual subscribers are entitled to a copy of the reports gratis. The association originated in a general feeding of the The association originated in a general feeling of the low state of science in England, and the first meeting, which was held at York in 1831, was brought about mainly through the instrumentality of Sir David Brew-Large sums are annually expended by the association in grants to individuals to enable them to prosecute scientific inquiries in particular directions.

BRITISH GUM.-British gum, or dextrine, as it is usually called, from the property possessed by it of rotating a ray of polarized light to the right, is simply torrefied starch. To prepare it, it is only necessary to torrefied starch. To prepare it, it is only necessary to heat starch to a temperature of 300°, until it assumes a buff colour. Starch consists of a soluble substance contained in an insoluble envelope. By exposing it to heat, the envelope is broken, and the soluble matter is set free. (See STARCH.) It is much used by calicoprinters and dyers for thickening dyes and stiffening

fabrica

Barrien Museum.-This great national institution owes its foundation to the will of Sir Hans Sloave, who, during a long and successful career as a physician in London, had accumulated, in addition to a considerable library of books and MSS., the largest collection of objects of natural history and works of art of his time, These he directed, on his death, which took place in 1753, to be offered to the British government for .220,000, which he balieved to be not one-fourth of their value. Fortunately, the offer was at once accepted. The act 26 Geo. II. c. 22, which authorized their purthe act 26 tee, 11. c. 22, which authorized their purchase, directed the purchase also of the Harleian collection of MSS, for £26,000, and enacted that the Cottonian library, which had been given to the government for public use in the reign of William HII., should, with these, form one general collection. This act dis-

rected, that for these purposes the sum of £100,000 be raised by means of lottery, leaving sufficient funds available for the purchase and fitting up of premises aveilable for the purchase and fitting up of premises for receiving them, and for originating a permanent insome. In the spring of 1754, the mansion in Great Eussell Street, then known as Montague House, was purchased as a repository for the whole, and between 1765 and 1759 the different collections were removed into it. Trustees were appointed, and the new institution received the name of the British Museum. It was first opened for public inspection on the 16th January, 1759. A nucleus having been formed, the nucleus rapidly increased, and it became evident that additional accommodation would be necessary. arrival of the Egyptian antiquities from Alexandria in 1801, and the purchase of the Townley marbles in 1805, rendered additional accommodation indispensable, and a gallery, adequate for both, was completed in 1807. The douation by his mejesty George IV. of the library of his father, George III., in 1823, led to active steps being taken for the crection of an entirely new museum. plans of which were ordered by the government to be prepared. Sir Robert Smirke was accordingly emprepared. Sir Robert Smirke was accordingly em-ployed to prepare the plans, and in 1823 the eastern wing of the present building was finished and occupied by the Royal library. The other portions of the new building were gradually proceeded with, and in 1817 the northern, southern, and western wings were issished. The style of architecture adopted is the Grecian Ionic. The principal front of the building is towards the south, facing Great Russell Street. It consists of a great central portico, with an advancing wing on either side, giving to the entire front an extent of 370 feet, the whole of which is surrounded by a columnade consisting of 44 massive columns. The columns are five feet in diameter at their base and 45 feet high; 12 stone steps, 120 feet in length, leading up to the portice. In the pediment are groups of allegorical figures by Sir Richard Westmacott, representing the progress of civilization. On either side of the Museum there is a semi-detached house, containing the residences of the chief officers of the establishment, giving an additional length of 200 feet to the front, and making its entire length 570 feet. The building, on its southern and eastern face, is inclosed by a renaissance iron railing, painted in imitation of bronze, and terminated by gilt spear-heads. An outer iron barrier runs the entire length of the front of the building. The building, as erected by Sir Robert Smirke, consisted of four ranges of apartments,west, north, and south, and inclosed a large open west, north, and south, and incosed a large open quadrangle in the centre. The southern range con-tains the great entrance-hall and staircase. The en-trance-hall is 62 feet by 51, and 31 feet high, and is ornamented by four marble statues,—Chantrey's Sir Joseph Banks, Roubiline's Slakspere, Nollekon's bust of Townley, and Westmacott's Mrs. Damer. To the west of the hall is the principal staircase, leading to the galleries; the centre flight is 17 feet wide, flanked by two pedestals of grey Aberdeen granite intended to receive colossal soulptures. On the first landing are pedestals and carred vases of Huddlestone stone. To the east of the lank in the southern range, on the lower floor, is a room containing the Grenville library; and to the west a saloon, containing antiquities. eastern range, besides some apartments appropriated to MSS., has a magnificent apartment, 300 feet long and 40 wide, containing the Royal library. The northern range of apartments is ellotted to the general library, one of the rooms, the 'main library' being 64 feet by 80, and having a striking appearance. The western range has one magnificent apartment, 300 feet western range has one magnificent apartment, 300 feet in length, centaining Egyptian and other sculpture. The whole of this extent of building on the lower or priscipal floor is of the height of 31 feet, and lighted by large windows, which are at the height of nearly 14 feet from the floor. Ascending the grand staircase we'reselve the upper floor, containing antiquities and natural history collections. The division of the south-

apartments on the upper floor, while of goodly a sions, and well adapted for the purposes they present, architecturally, no striking features, are fitted up with glass cases against the walk table-cases in the centre, for the cribinition of the objects. They are also lighted from a su arrangement which, while it affords more walf-for the exhibition of the objects, likewise adm their being seen to greater advantage. Such we great edifice planned by Sir Robert Smirks, while the time of its being funished, was regarded as the the time of its being finished, was regarded as the of the non-ecclesiastical buildings in the metropolis; but before it had reached completion it was found to be insufficient for the rapidly-increasing wants of the museum. A callery, or saloon, for the Eight marbles was constructed to the west of the western range, and further accommodation for the library was obtained by building what is called "the arch-room," an addi-tion to the western side of the northern wing. Various other additions have since been made, the most impor-tant of which is the new Reading-room, of which it is scarcely possible to speak in too high terms of admira-tion. It occupies the quadrangular space in the centre of the building, and is connected with the entrance-hall by a long passage. At least thirty feet of the quadrangle are left all round, to give air and light to the surrounding buildings. The plan of the new reading-room was suggested by Mr. Panizzi, the present principal librarian, and was carried out by Mr. Sidney Smirke, brother of the architect of the main building. The first parliamentary grant for its construction was voted in 1854, and it was opened in 1857, the entire cost, including the littings and furniture, amounting to about £150,000. It is circular in form, and is constructed principally of iron, being covered by a magnificent dome, the largest, with one exception, in the world. The diameter of the floor is 140 feet, and the height from the floor to the top of the dome is 106 feet. The dome exceeds in diameter either that of St. Paul's or of St. Peter's at Rome, and is only surpassed by that of the Pantheon at Rome, which has a diameter of 142 feet. It is, perhaps, to be regretted that the architect did not cularge its dimensions by a few feet, so as to render it indisputably the largest dome in the world. The room is lighted from above by a range of 20 windows, 27 feet high and 12 feet wide, running round the done, and by a lantern-light, 40 feet in diameter at the top. The walls are lined with books to the height of 25 feet, accessible either from the floor or from two rows of galleries, which run round the apartment. The books accessible from the floor are chiefly books of reference for the use of the readers, who may consult them without applying to any of the attendants. About 20,000 volumes are in this way at the service of the readers. Should a reader require any other book in the library, he has only to copy out its title and number from the catalogue, adding the date, his own name, and the number of his seat, on a ticket provided for the purpose, and in a short time the volume or volumes are placed noislessly at his side. Each reader has a table four feet three inches long, carefully marked off, and fitted up with every convenience for reading and writing; and there is accommodation for about 300 readers. Even this large number of seats is becoming too small for those that seek to avail themselves of the use of the room, and of late numbers have had, on particular occasions, more especially on the Saturday afternoons, to go away disappointed, the seats being all occupied. Those who have occasion frequently to avail themselves of the reading-room and library are best able to estimate the value of the boon which they enjoy; and much praise is due to Mr. Panizzi, who not only conceived the original design, but constantly superintended the progress of the work, frequently suggesting improvements and alterations as it went on. Notwithstanding the great additions made to the Museum, a strong demand still exists for more we reset the upper floor, containing antiquities and another to the west of the staircase, is occupied by antiquities, while botany occupies the division of the southests. The western range is also occupied by antiquities, while botany occupies the division to the east. The western range is also occupied by antiquities, the northern purity by mineralogical specimens and partly by zoological objects, the latter also occupied by antiquities; the northern purity by mineralogical specimens and partly by zoological objects, the latter also occupied by antiquities; the northern purity by mineralogical specimens building, or by removing some part of the order to the eastern range is also occupied by antiquities. When one is the proposal for obviously control of the southern proposal for obviously, and this difficulty, either by the extension of the present building, or by removing some part of the order to the control of the proposals is the east. The western range is also occupied by antiquities, while botany occupies the division to the control of the proposals is the east. The western range is also occupied by antiquities, while botany occupies the division to the control of the order of the control of the proposals is the east. The meters of the control of the order of the control of the order of the

of the most valuable documents of this collection is the Codex Alexandrinus. (See ALEXANDEIAN MANU-SCRITT.) The Lansdowne collection of 1,245 volumes

was purchased in 1805, and the Hargrave collection,

was pareimsed in 1900, and the rangiage confector, achiefly connected with law, in 1813. The Burney collection of 520 volumes is chiefly noted for its copies of the ancient classics. The Royal library of George III. brought with it about 440 volumes of MSS. Francis Henry Egerton, the last earl of Bridgewater, bequeathed to the Museum 67 MSS. together with 25,000 and 27,000; the interest of the former sum to

be spent in adding to the Egerton collection, and that of the latter to pay the salary of an Egerton librarian. To 1833 the Arundel collection, comprising 600 volumes, was obtained from the Royal Society. It is particu-

tarly rich in works bearing upon the early history of the people and language of this country, and contains large assemblage of books of civil and canon law.

These are the principal collections in this department; but there are numerous others obtained either as dona-

tions or by purchase, and containing many works of interest and value. The Department of Prints and

Interest and value. In Department of Prints and Densities comprises those bequeathed by the Rev. C. M. Cracherode, in 1790; by Mr. Riebard Payne-Knight, in 1824; the Sheepshanks collection of Dutch etchings, purchased in 1836; and numerous smaller collections,

sained by gift or by purchase. Latterly this depurtant has been increasing as rapidly as any in the

ing as rapidly as any in the

prised three departments only,—printed books, manuscripts, and natural history, the last including antiscript, and natural natury, the last including and quities, works of art, &c. From time to time the number has been increased, so that now there are eight de-partments; vis., printed books, manuscripts, prints and drawings, antiquities, soelogy, botany, geology, mineratory. Over each of these departments is a chief officer, called a keeper; those of natural hisconset officer, called a keeper; those of natural his-bory having also a superior officer, called a superin-tendent. The Printed Book Department.—The ori-ginal bequest of Sir Hans Sloane, amounting to about 50,000 volumes, soon received a valuable addition in the Royal history, which had been accumulated by the sovereigns of England from the time of Henry VII. downwards. This library was presented to the Mu-seum by George II. in 1757. The collection itself and large, numbering only some 10,500 volumes; but it was valuable, as comprising the libraries of some eminent individuals, as Archbishop Cranmer and Issac Casaubon. At this time it also received the right to a copy of every work entered at Stationers'—Hall. In 1763 it received from George III. a valuable collection of pampillets relating to the civil wars of England between 1640 and 1660, made by George Thomason, a bookseller of the time in St. Panl's Churchyard. In 1823 the splendid library of George III., col-lected during his long reign, at an expense of about \$150,000, was presented to the Museum by George IV. The most important of the recent additions was that bequeathed by the Right Hon. Thomas Grenville, in 1346, consisting of 20,240 volumes, collected at an expense of upwards of £54,000. Besides bequests and donations, the library has been largely increased by purchases, and is now one of the largest collections of books in the world, being estimated to contain (1862) upwards of 600,000 volumes. Manuscript Department .-The history of the manuscript department in general resembles that of the printed books, though its growth has been much less considerable. The Cottonian, Sloanean, and Harleian collections formed the nucleus of this department. The Cottonian collection, made by Sir Robert Cotton, who died in 1631, is particularly rich in Anglo-Saxon MSS, and documents referring to the early history of Britain. Many of the works for-merly belonged to monastic libraries. The Sloanean collection consists of 4,100 volumes, relating chieffy to medical and natural-history subjects. The Harleian collection is of a very miscellaneous character, in-collection and collections of the control of the contr the sacient classics, illuminated missals, and poems, essays, ballads, plays, "in almost every modern language." It consists of about 7,600 volumes, besides 14,900 original rolls, charters, deeds, and other legal decuments. In 1757 another collection was added,—that of the MSS. of the Royal library of England, com-prising about 1,950 volumes, many of which were ob-tained from the monasteries on their destruction. One

## British Museum

Museum. Of the Italian school, there are original drawings by Michael Angelo, Raphael, Paul Vero-nese, Tintoretto, Leonardo da Vinci, Correggio, and others. The German school contains drawings of Peter Vischen Albert Duran Manual Hall Vischer, Albert Durer, Hans Holbein, and others. The Dutch school is represented by one or two superb drawings by Rubens; also numerous specimens of Van Dyck, Rembrandt, Oatade, Teniers, Paul Potter, and A. Cuyp. The French school is represented by numerous drawings by Claude Lorraine and others; and the Spanish by some of Murillo, and others of less note. Among the engravings are a number of speci-mens of the Italian school, including works by Botti-celli, Leonardo da Vinci, Raimondi, and others. Of the German school there are specimens of Lucas Cranach, Murtin Schongauer, Albert Durer, and Cranach, Murtin Schongauer, Albert Durce, see others. The Dutch school is represented by engravings by Lucas van Levden, Van Dyck, Teniers, Rembrandt, Ostade, &c. This department contains, also, branch of works in nielle, an extensive and valuable collection of works in niello, and of sulphur casts. The Department of Astiquities.— The collection of antiquities, which was at first so small as to be regarded merely as an appendage to natural history, now occupies more space than any other department except the library. It is divided into two classes; the one consisting of sculptures, including inscriptions and architectural remains, the other the smaller remains, of whatever nation or period, as vases, terra-cottas, bronzes, coins, medals, domestic utensils, ornaments, &c. The first considerable addition to this department was made by the purchase of the collection of Greek and Roman antiquities made by Sir Hamilton. The Egyptian antiquities brought from Alexandria in 1801, and the Townley marbles purchased in 1905, added largely to the collection; and in 1807 the antiquities were made a distinct department. 1815 an extensive series of sculptures, the frieze of the temple of Apollo Epicurius (or the deliverer), near Phigalia, in Arcadia, was purchased by the Prince Regent, and ordered to be deposited in the Museum. To these were added, in 1818, the Figir collection, consisting chiefly of excellent sculptures from Athens, purchased by government from the earl of Eigin for £33,000. Since that time numerous adof Eight for \$25,000. Since that the numerous activities have been made to this department, particularly in the Assyrian antiquities obtained by Mr. Layard and others, and the sculptures and other antiquities obtained from the mausoleum of Halicarnassus. The sculptures are on the ground floor, and consist of Egyptian, Assyrian, Greek, and Roman remains. The Egyptian sculptures are of basalt and granite, and some of them date from 2,000 years before Christ. They represent human and allegorical figures, usually of colossal size, and inscribed with hieroglyphics. The smaller Egyptian remains are in a gallery on the upper floor. The Assyrian antiquities were obtained by a series of excavations conducted by Mr. Layard during 1847-50, and more recently by Messrs. Rassam and Loftus, at Nimroud, Koyanjik, Korsabad, &c. The monuments consist chiefly of slabs sculptured in slight relief, exhibiting warlike encounters, triumphal marches, &c., and frequently covered with canciform characters (which These monuments are exhibited in a suite of three long narrow rooms, recently erected, together with a large apartment on the basement. The Grecian antiquities are contained in three apartments communicating with the Egyptian gallery, known as the Lycian, Elgin, and Phigalian galleries. The Lycian apartment Eigin, and Phigalian galleries. The Lycian apartment contains sculptures brought from Lycia, 1842-46, by Sir C. Fellowes, and ranging in date from the subjugation of the country by the Persians, B.C. 545, to the period of the Brzantine empire. The Klgin and the Phigalian galleries are so called from containing the Elgin and Phigalian marbles, which constitute the most important part of their contents. The collection of Roman antiquities embraces an interesting series of busts of various dates, arranged in chronological order, running down one side of the gallery; while, on the other, are mosaics and other remains discovered in this country. In the Graco-Roman saloon are antiquities found in Italy, but which bear unmistakable evidence of Greek origin. Among the smaller collections is that of vases, comprising numerous appoint mens of Phonician, Etruscan, Greek, and Roman

## British Museum

workmanship. The bronzes are numerous, comprising a great variety of articles of Greek, Etcuscan, and Roman manufacture. The British and Mediswal col-lection illustrates the condition of the arts in our own were made of flint, through the Anglo-Saxon and Norman periods, down to the Middle Ages, when works of art were produced which excite wonder and admiration even in the present day. The Ethnographical collection embraces articles now, or formerly, in use among nations other than European. The Ethno-Connected with the Antiquity department is the col-lection of coins and medals, which is very rich and valuable. They are arranged into ancient, mediæval, modern, and oriental, and are kept in one room, called the "Medal-room," no space having yet been found for exhibiting any of them to the public. Of the Zoological department it is almost impossible to say anything without being led into details, which our limits strictly forbid. According to the statement submitted to her Majesty's commissioners of inquiry in 1849 by Dr. Gray, after visiting the continental collections, he believes that the Museum collections of mammalia, birds, shells, and lepidopterous insects, are much more extensive than any other public collection, and superior to all the public collections together. This is certainly the case with the first and last-mentioned groups, and he believes also with the other two. The collections of reptiles, fish, and crustaces, are second only to those at Paris, if at all below them;" but "the Museum collection in each of these classes contains many species which the Paris collection wants. The Museum collection of insects, taken as a whole, is much larger and better arranged than that of Paris... The collections of corals, sea-eggs, and starffshes, are very large, far larger than those of all the other European collections together." Since that time the various collections have been largely increased. The Botanical callection is very extensive. The nucleus of this de-partment was formed by the herbarium collected by Sir Hans Sloane, bound in 262 volumes, and comprising about 8,000 specimens collected in Jamaica and else-In 1827 it received, as an addition, the magnificent collection of Sir Joseph Banks, at one time the most valuable assemblage of dried plants in Europe. Since that time the additions to this department have been numerous, so that it now contains upwards of 50,000 species of plants, and in point of value to the botanist is second to no other collection in the world. Since 1858 a portion of this collection has been exhibited to the public. The Geological or Palacontological department contains an extensive series of fossil remains of plants and animals from the various fossiliferous strata. It has been mostly formed within the last quarter of a century, the first great contribution to it being the celebrated collection of Dr. Mantell, in 1839. It has since received large additions. The fossils and minerals together occupy six rooms of the north gallery of the Museum, the fossils being mostly disposed in wall-cases around the rooms, and the minerals in table-cases in the centre. The mineralogical collection, which is large and is rapidly increasing, is arranged according to a chemical classification, which, however, is not fully up to the present state of the science, and a re-arrangement is in contemplation. The management of the Museum is vested in a body of trustees amounting to forty-nine in number. The three principal trustees are the archlishop of Canterbury, the lord chancellor, and the speaker of the House of Commons, in whom is vested the patronage to the various offices, except that of principal librarian. There are twenty-two other official trustees; nine are representatives of the families of distinguished donors; and lifteen are elected by the other trustees. At first, the admission to the Museum was by means of printed tickets after written application; and the visitors were hurried through the several departments by attendants, not more than fortylive visitors being admitted per day. From time to time more liberal measures have been adopted, and now all who present themselves are freely admitted. The Museum is open daily during Easter, Whitsun, and Christmaa weeks, and on Mondays, Wednesdays, and Fridays, in every other week, except the first week of January, of May, and of September, when it is closed. In summer, it is open from 10 to 6, in winter from 10

## Broad-sword

to 4; and during the months of March, April, Se to 4; and during the months of March, April, September, and October, from 10 to 5 o'clock. The satisfact and October, from 10 to 5 o'clock. The satisfact and the satisfact and the satisfact and the satisfact and taxes, £520; fact and light, £1,300; stationers, £300; purchases and acquisitions, £22,330; bookbinding, £00, £10,910; printing catalogues, &c., £4,400, buildings, repairs, &c., £10,331; furniture and fittings, £8,131; incidental expenses, £1,020. The expenditure of the financial year 1369-70 was £13,823 in excess of the preceding year.

BRITISH NAYY. (See NAYY.)

BRITISH NAVY. (See NAVY.)
BRITISH NAVY. (See NAVY.)
BRITISHNES, brit'-tl-ness (Ang.-Sax.), a property
possessed by some bodies, which, although solid, have
their component particles so arranged, that the ophesive force which holds them together is overcome by com-paratively small mechanical force. They can easily be reduced to powder. Britteness is the reverse of mal-leability: as an instance, lead is malleable and glass is brittle.

(See DIATOMACEE.) BRITTLEWORTS.

BRITLEWORTS. (See DIATOMACEE.):
BRIZA, bri'.za' (Fr. brizo, I nod, on account of the quaking character of the spikelets), in Bot., a gen. of grasses, commonly known as Quaking-grass, or Maideniar. Two species are natives of Britain, the B. major and minor. Their dense clusters of flowers hang upon the ends of very delicate filamentous pedundes, forming elegant panicles, which shake with the slightest breath of air

BRIZURE, briz'-ure (Fr. briser, to break), an expi sion in Her., used in reference to any charge that is in a broken condition, or bruised. The terms brize and

brief are used synonymously.

Broach, or Broche, bruche (Fr. broche, a spit), a name given in Arch. to a small steeple or spire that is built on the top of a tower, rising immediately on the summit of its walls, without being surrounded at the base by a parapet or battlements.

Broad Arrow, broad-ar'-ro, in Her., a charge repre-enting an old-fashioned arrow-lead, consisting of a hollow central spike from which side-pieces diverge in monow central spike from which ands-pieces diverge in the form of the letter V, the outer edges of which are perfectly straight, and the inner engraised. In heraldic phraseology, the broad arrow is commonly called a

Pheon.

BROAD ARROW, in Mar., a mark formed by three lines broader at one end than the other, meeting together in a point. It is stamped or cut on all timber or metal used in her Majesty's dockyards, and on all or ment used in her algesty a lockyards, and on mand stores that will bear incision or impress, belonging to the crown, that they may be identified if stolen. Sails and ropes are marked by the intermixture of a coloured thread or yarn. Thread of

a different colour is used in each of her Majesty's dockyards; so that any storekeeper can not only tell that the material is the pro-

ARROW.

BROAD

perty of government, but also say in what dockyardit was made. It is unlawful for any one to have stores bearing the broad arrow, or any other govern-ment mark, in his possession; and an act was passed in 1698 by which a fine of £200 and costs is inflicted on any one on whose premises property so marked may be found.

IROADSIDE, broad side (Ang.-Sax.), in Mar., is precisely the same as would be called by soldiers a volley, i.e., the discharging of the whole of the guns contained in one side of a ship at the same moment. The weight of shot and shell that can be delivered by the broadside of a line of buttle ship is very great. the broadside of a line-of-battle ship is very great; the Duke of Wellington, of 131 guns, can fire off at one broadside a weight of metal amounting to 2,400 lbs. When a vessel is pressed down on one side in the water by the wind, she is said to be on her broadside. the

Broad-sworn, broad-sord, a sword with a broad blade, designed chiefly for cutting, but capable of being used, like the rapier, for thrusting. When made so as to be employed in the latter way, as well as for cutting, it is called a sabre, and forms one of the weapons of the English and continental cavalry soldier. The modern representatives of the old English broad-sword is the clavingre, with which the Highland regiments in the English service are still armed. The English became more and more skilful in the use of the broad-sword, according as the wearing of suits of mail began to grow out. It was a common weapon in the

\* 61

days of Queen Elizabeth, and the "swash-bucklers or "bullies," of that period achieved on unenviable notoristy for their skill in it. The buckler, or shield, a nedgraty for their skill in it. The buckler, or shield, a very ancient article of smour, generally accompanied the broad-sword, forming as it did the principal means of defence against it. At the close of the 16th century, award-and-buckler flekting began to grow out of use, having been superseded by the continental mode of flekting with the rapier, or thrusting sword, and the dagger. The Highlanders, however, continued to us the weapon, as well as the larget or buckler, until they were disarred after the right of 1745. With the Scotch Highlander and was termed the clay. Highland Clans the broad-sword was termed the claymore, and it was their national weapon. Sir Walter Scott, in the "Ludy of the Luke," gives several spiritairing descriptions of combats with the claymore and tanget. As has been stated, the sabre used in the cavalry regiments at the present time is a broad-sword with a point sharpened for thrusting. Every recruit is taught to use the weapon so as to make it a formidable instrument of destruction in warfare. In the accompanying illustration is shown a reduced model of the sabre-

BROADSWORD TARGET.

target. The lines within the circle denote direction the in which the cuts" are to be made. Cut1 is directed diagonally through the target, coming out at 4; 2 is the cut same, only from left to right; wards, diagon-ally, and 4 is the same, only in the opposite

direction: cut 5 is horizontally through the target, from right to left, and 6 from left to right; out 7 is perpendicularly downwards. All these cuts are fairly given with the edge of the broad-sword. The swords drawn upon the target represent the guards. There

are seven cuts, seven guards, and three points.

BEOCADE, bro-kaid' (Sp. brocado), a stout siken, variegated with gold and silver, raised and enriched with foliage, flowers, and other ornaments, and used for the dresses of both sexes during the 17th and 18th centuries. In an inventory of the wardrobe of Charles II., in the Harleian library, is mentioned white and gold brocade at two pounds three and sixpenns per yard, and collere-du-prince brocade at two pounds three shillings per yard." Brocade was not known in England till after the 13th century, and was a great rarity and luxury upon the continent in the

BROCAGE, broe'-dj (Ang.-Sax.), is the hire or com-mission due to a broker or agent, for managing a transaction frequently of a mean or unlawful nature.

BROCAGE CONTRACTS FOR MARRIAGE, are contracts by which a reward is stipulated for the promotion of a particular marriage by means of exerting an influence over one of the parties. These contracts are in law held to be contra bonos mores, and can afford no ground of action.

BEOCARDS, BROCARDICS, OF BROCARDICA, bro'-kards Besockers, properly, maxims or principles in law, as the Becommics Juris of Azo; but it has come to be applied to maxims or proverbs generally. It is said by Vossius to be derived from the Greek term protrachia, first elements; but others, with more probability, derive it from Burchard, or Brocard, bishop of Worms, who ande a collection of canons, called from him Brocur-dies; and as they shounded in short sententious sayings and proverbs, the name came to be applied to works of that description.

Buccoon, brok o-te (Ital., spronts), the name given to one of the many cultivated varieties of the Brassica oleraces. It is a common garden vegetable, and differs from the carliflower only in having coloured instead of white heads. (See Brassica.)

Brown us, bro-shure' (Fr. brocher, to stitch), in a

term taken from the French, and used in the same sense as pamplifet; properly a stitched book.

Brochus, or Brochus, bro'-kus (Gr., a snars).

medical term, denoting a noose, or a particular kind of bandage. It is also used to signify a person having inordinately thick lips, or whose teeth project for-

BROGUE, or BROG, brogue (Irish), was a sort of rude, clumsy shoe, formerly worn by the native Irish and the Scotch Highlanders. From the manner in which the wearers of brogues pronounced the English language, the term came to be applied to their pronunciation.

Broken-backen, bro'-kn-bak'-ed, in Mar., a term

applied to the state of a ship so loosened in her frame, either by age, weakness, or some great strain, as to droop at each end.

BROKEN-WIND, a disease or unsoundness in borses, caused by a morbid secretion from the mucous mem-brane lining the laryux and the windpipe, with its many ramifications. The nature of the disease is not well understood, and the present mode of treating it is very unsatisfactory. Broken-wind is in reality curable; and all that a veterinary surgeon can do is to Low-bred horses, which do not mitirate the disease. thrive, are most liable to broken-wind. While the horse is being exercised, the symptoms can be best observed. The eyes become suffused with blood, which is mostly inpure, the postrils are distended, and the breathing becomes very laboured. Horse-dealers some times try to conceal the defects of a broken-winded horse by making him swallow grease. The effect. however, soon passes away, and it is therefore only the very ignorant and unwary who are thus deceived. A broken-winded horse has always a hollow cough, and, if watched while at work, the ribs are noticed to be actively moved, and after the air is expelled from the lungs they are depressed with a sudden jerk, produced by the abdominal muscles. When employed on hard work, broken-winded herses often drop down and die from exhaustion or from suffication, internal hemorrhage, or congestion of the lungs. The disease of broken-wind was much more common in former times than at the present day; it is now found principally in those countries where horses are budly managed and coarsely fed.

BRORER, bro'-ker (Ang. Sax.), is a person employed as an agent to transact business between merchants or others, usually in the interest of either the buver or seller, but sometimes acting for both parties. Generally, brokers confine themselves to the purchase and sale of some particular articles, or class of articles, by which means the; obtain a more intimate knowledge of their qualities, market value, &c., and are thus able to negotiate on more favourable terms for their employers. A merchant trading in a variety of articles cannot have the same intimate knowledge for his guidance; and bence generally finds it for his advantage to effect his purchases and sales by means of brokers. Brokers are of different kinds, according to the branches of business to which they devote themselves; as bill-brokers, exchange-brokers, insurance-brokers, ship-brokers, pawubrokers; all of whom will be found noticed under their special heads in other parts of this work. In London, every person desirous of acting as a broker must be licensed by the lord mayor and aldermen for that purpose, under such restrictions and limitations as they may think fit to enact. When admitted, he must give bond, under a penalty of £500. for the faithful discharge of his duties, without fraud or collusion, and to the utmost of his skill and knowledge. He is further bound not to deal in goods on his own account—a stipulation which is very commonly broken. Each broker pays on admission a fee of £2. and a like sum annually, so long as he continues to act.

Any person acting as a broker without being duly licensed, is liable to a penalty of £100 for each transac tion; but the law is frequently evaded. Every broker is bound to register regularly in a book all the contracts which he has entered into. The term broker is also usually applied to persons who buy and selisecond-hand household furniture, though such as occupation bears little analogy to that which we have been describing, as these parties generally buy and sell, not as scents, but on their own account. Such persons irequently superaid to their business the appraising

#### Brokerage

and reling of goods distrained for rent; for the per-formance of which functions, however, they must prowide themselves with an excise license, and conform to the regulations enacted by 57 Geo. III, c. 93.—Ref. Macculloch's Commercial Dictionary; English Cyclo-

Pediu-Arts and Sciences.

BROWREAGE, bro'-ker-ij, is the pencentage or commission charged by brokers for the sale or purchase of

Brown, bro'ma (Gr. broke, I eat), denotes food of any kind that is masticated; and hence bromatology is

a discourse on food, bromography a treatise on food.

Browal, bro'mül, in Chem., a compound formed by the action of bromine upon alcohol. It is a colouriess oil, of spec. grav. 3:35, and is analogous in its composition and properties to the corresponding compound of chlorine,—chloral (which see).

Brown-Grass. (See Brown's.)

BROWNELGARS. (ore Discounts.)
BROWNELLS, bro-me'-b'-a (numed after Bromel, a Swedish hotenist), in Bot., the typical genus of the nat, ord. Bromeliscew. The green fruit of B. pingnin is used as an anthelmintic and a diuretic in the West Indies: the prickly leaves yield strong fibres, which are twisted into ropes, and woven into coarse cloth.

BROMELIACEM, bro-me-li-ai'-se-e, in Bot., the Bromelia or the Pine-apple fam., a nat. ord. of monocotyledonous plants, sub-class Petaloidea. They are herbs or somewhat woody plants commonly epiphytical. Leaves persistent, crowded, channelled, rigid, sheathing at base, and frequently scurly and with spiny margins; flowers showy; perianth superior, or nearly or quite inferior, arranged in two whorls, the outer of which has its parts commonly united into a tube, while the inner has its parts distinct, imbricated, and of a different colour; stamens 6; anthers introrse; ovary 3ceiled, with a single style; fruit enpsular or indehiscent, and 3-celled; embryo minute, in the base of mealy albumen, with the radicle next the hilum. There are 29 genera and about 175 species, which are dis-tributed through the tropical regions of America, West Africa, and the East Indies. They are chiefly important for yielding edible fruits and useful fibres. Some have anthelmintic properties, and others contain colouring matters. (See Ananassa, Brownlia, Bill-

BERGIA, TILLANDSIA.)
BROMIC ACID, bro'-mik, symbol BrO, equivalent 120, the only known compound of bromine and oxygen. It corresponds in composition to chloric acid, but has never been obtained in an auhydrous condition. combination with water it forms a colourless liquid, which first reddens and then blesches litmus. bases it forms bromates, which are similar in their

properties to chlorates.

BROMINE, bro'-mine (Gr. bromos, a stench), symbol Br, equivalent 80, spec. grav. 2:908. Bromine is an elementary substance, consisting of a heavy mobile fluid of a deep brownish-red colour. When exposed to the air, it volatilizes rapidly, and boils at 145° Fahr. Its smell is disagreeably pungent, giving rise to a painful spasm of the glottis, if breathed. It acts energeticaily on the skin, producing a sore immediately on contact. At -7° Fahr, it solidifies into a yellowish-brown crystalline mass. It was discovered in 1826, by Balard, in minute quantities in sea-water, in which it exists as bromide of magnesium. It also occurs in a native bromide of silver found in Chili, and in union with various alkalies in certain mineral waters. It is prepared by passing chlorine through a solution of alkaline bromides, until the yellow colour produced remains uniform. Ether is added, which isolates the bromine. This is separated from the saline solution and shaken up with a solution of caustic potash. The solution is then evaporated to dry-ness, and the residue distilled with binoxide of mangenese and suphuric acid. Bromine is the only element that is liquid at ordinary temperatures, except mercury. The properties of bromme resemble those of chlorine; but they are somewhat less strongly developed. It bleaches regetable colour, and is a nondeveloped. It beaches regenence colour, and is a non-supporter of combustion. It is slightly soluble in water, giving to it a vellow colour. It combines with water and forms a hydrate, which crystallizes in actahedra at 32° Fahr. The principal compounds of bromine are hydrohromic acid, a compound of one diluent drinks, as barley-water or linesed tes, given, squiralent each of hydrogen and bromine. The action it is frequently necessary to have recourse to blood.

## Bronchitis

of hydrobremie sold on metallic exides is p similar to that exerted on them by hydrocaler. Thus, hydrobromic acid and potests combine, if bromide of phiassium and water. Hydrobrom bromide of potassium and water. Hydrotromac sure is soluble in water to a considerable extent. It is colourless, strongly acid, and suffers no charge on corposure to the sir. On the addition of nitrio seid, decomposition takes place, and a bromic squa resist in formed, which, like the chloric squa regist in the charge of the compound, bromic acid (which see). With chloring, bromic forms a chloride, a reddish, vellow rotation to the chloride. bromine forms a chloride, a reddish yellow rotallishiquid, soluble in water, and possessing bleaching properties. It also unites in the account of the control of the contr perties. It also unites, in two proportions, with phosphorus and iodine. With sulphur, it forms a single bromide. None of these compounds merit notice. Bromine and its compounds are extensively employed in the daquerective and collection processes. In the in the daguerrectype and collection processes. former, it reduces the time of exposure from minute to seconds. Bromide of potassium is also used in medicine.

BROMORORM, bro'-mo-form, a compound of bro-mine and formyl, corresponding to chloroform, which is a compound of the latter radical with chlorine,

BROMUS, bro-mas (Gr. hromos, wild oat), in Bot, Brome-grass, a gen. of plants belonging to the nat, ord. Graminacea, characterized by the flowers being in lax panicles; the glumes many-flowered; the outer pales bifid at the extremity and awned beneath; and by the very short stigma growing from the face of the germen beneath its apex. Many of the species are very common British grasses. Some have erroneously

been reputed to be purgative.

BEONCHI, bron'-ke (Gr. bronches, the windpipe), Dancest, oron-ke (or. oroncoo, the windsper, in Anat., is the name given to the subdivisions of the trachen, or windpipe, which proceed to the lungs. The trachen divides into the two bronch opposite the third dorsal vertebra. The right bronchus is larger than the left, and is shorter, reaching the lung on a line with the fourth dorsal vertebra. The left bronchus passes under the arch of the aorta. The structure of the bronchi is similar to that of the traches, being round and cartilaginous in front, and flat, with mus cular and fibrous tissue, behind. On entering the substance of a lung, the bronchi divide and subdivide into numerous branches, till they terminate in very minute air-cells.

BRONCHITIS, bron-ki'-tis, or inflammation of the lining membrane of the bronchial tubes, is one of the most prevalent and fatal diseases in this country. great exciting cause is cold, especially when combined with moisture; but whatever tends to diminish the general vigour of the system, and excesses of every kind, predispose to it. Any sudden change of ten-perature is apt to produce it. It is especially preva-ient during the spring months. Its first symptoms are generally those of a common cold, accompanied with an occasional cough and a sense of weariness and headache. The cough increases, and there is a feeling of oppression in the chest, and the breathing produces a kind of wheezing noise. The pulse is rapid and weak, and there is extreme lassitude, with pain in the limbs, mental heaviness, &c. If the feverish symptoms increase, the breathing becomes difficult from the clog-ging of the tubes with mucus, which is, to some extent, expectorated during the cough. In severe cases, the symptoms become more and more alarming; the breathing becomes so emburrassed that the patient can no longer lie down, but requires to maintain an upright posture and use all his muscles in respiration. At last, he is so exhausted that he ceases to expectorate, and dies of suffication from the accumulated mucus, usually in from five to seven days. Even in less severe cases, the delicate respiratory tubes are frequently permanently injured; so that the proper acrasica of the blood is interfered with. The treatment of this disease will vary, according to its nature and the constitution of the patient; and the necessity of always having recourse to a medical man cannot be too strongly insisted upon. The great object of the treatment is to reduce and remove the inflammatory condition of the organs: hence a mustard poultice should be applied to the chest, the feet bathed in hot water, and warm

#### Bronchocele

letting and to administer emetics, in order to remove ieting and to administer emetics, in order to remove the accumulations of mueus. The howels should be kept moderately open during the whole course of the disease. (See Cataram, Course.) BRONGHOUSE. (See GOTTE.) BRONGHOUSE. (See GOTTE.) BRONGHOUSE. drive ET.), an alloy of copper and tin, to which are sometimes added small portions of zinc and lead. Got hell seed.

lead. Gun, bell, and speculum metal partake much of the nature of bronze. The manufacture of bronze is very ancient, having been brought to a considerable state of refinement 700 years before the Christian era. The ancients used it for weapons and tools, on account of its great hardness; but it was at length superseded for these purposes by steel, and is now only employed for statuary and medals. For the former purpose, bronze is particularly well fitted, being tough, hard, little affected by atmospheric influence, besides possessing the valuable property of flowing freely v melted, and expanding when solidifying; by which means the most intricate detail in the mould is copied with sharpness. Bronze may be tempered in an ex-actly contrary manner to steel. If cooled suddenly, it becomes so soft that it may be hammered and turned in the lathe; but if allowed to cool slowly, it becomes brittle, hard, and clastic. In casting large statues or other works, the greatest skill and care are necessary, from the circumstance that alloys of copper and tin have a tendency, when melted, to separate, the tin rising to the top of the melted mass, and forming a more fusible mixture. From the following analyses, it will be seen that bronze differs greatly in composition: Anient bronze from Celtie antiquities,—tin, 12; copper, 88. Egyptian bronze,—tin, 22; copper, 78. Chinese bronze,—tin, 20; copper, 80. Roman bronze,—tin, 15; copper, 85. Modern bronze from the statue of Louis XV.—copper, 82:45; zinc, 10:30; tin, 4:10; of Louis XV.,—copper, 82:45; zinc, 10:30; tin, 4:10; lead, 3:15. (See also Bell, Speculum, and Gun-METAL.)

BRONZE, ALUMINIUM, is the name given by its discoverer, Dr. John Percy, F.R.S., to an alloy which promises to become of great value in the manufacturing arts. Mr. I. L. Bell, who has manufactured a large quantity of this metal, thus describes its composition:— Copper is melted in a plumbago crucible, and, after being removed from the furnace, the solid aluminium is added. The union of the two metals is attended with such an increase of temperature that the whole Decomes white-hot; and unless the crucible con-taining the mixture is of a refractory material, it is fused by the intensity of the heat. A vessel which has remisted a heat sufficient to effect the fusion of copper has been melted when the aluminium has been added. In a statement communicated by Lieut, Col. Strauge to the Astronomical Society, the following facts were put forth, which, in their condensed form, we borrow from the last edition of Ure's Dictionary of Arts, Manufactures, and Mines :- Regarding the most Arts. Manufactures, and Mines:—Regarding the most important qualities of the alloy as—1. Tensile strength; 2. Besiatance to compression; 3. Malleability; 4. Transverse strength or rigidity; 5. Expansive ratio; 6. Founding qualities; 7. Behaviour under files, cutting tools, &c.; S. Resistance to atmospheric influences; 6. Fitness to receive graduation; 10. Elasticity; 11. Fitness for being made into tubes; 12. Specific ir. Risess for being made ind to determine each of those conditions. Tensile strength.—The result of those conditions. Tensile strength.—The result of trials made by Mr. Anderson, of Woolwich, was—the average tensity of this metal proved to be 22 tons 12 owt. (50,624 lb. breaking weight per square inch. Blongation did not take place until 4,300 lb. in the one case, and 3,600 lb. in the other, had been applied, when a permanent elongation was noticed of '009 of an inch in the first specimen, and '034 of an inch in the last. Resistance to compression.—The ultimate amount of compression applied was upwards of 59 tons, under which the specimen became much distons, under which the specimen became much dis-terted. Compression was not perceptible until up-wards of 9 tons per square inch was applied, when the specimen gave way, but in the very slightest degree. On the weights being removed, a certain amount of elasticity was ramarked. Malleability.— The quality of this metal for forging purposes would appear to be stoclent. There were specimens in the International Exhibition of 1863, showing that the

### Bronze-Powders

alloy could be drawn out under the hammer almost to a needle-point. Transverse strength.—These experiments were made by Messre. Simms. The same weight applied to these bars altered the index of the instrument as under: Brass, 2:22 divisions; gun-metal, 0:15 of a division; aluminium bronze, 0:05 ditto. Heuce aluminium bronze is three times more rigid than gun-metal, and 44 times more rigid than brass, Expansive ratio.—Aluminium bronze is affected by change of temperature a little less than gun-metal, and much less than brass. Founding qualities. The alloy produces admirable castings of any size. Bekaviour under files, cutting-tools, &c.—In this respect it leaves nothing to be desired. It does not cleg the file; and in the lathe and planing-machine the tool removes long clastic shavings, leaving a fine, bright, smooth surface. Resistance to atmospheric influences, -This alloy tarnishes much less readily than any metal usually employed; viz., gun-metal, brasa, silver, cast iron, or seed. Fitness to receive graduation. -The lines are remarkably pure and equable, and very distinet under the microscope, notwithstanding the yellow colour of the metal. Elasticity.—No wires tried for the suspension of Foucault's pendulum for illustrating the rotation of the earth were so durable-not even, those of steel-under that severe ordeal, as wires of aluminium bronze. Fitness for being made into tubes .-It admits of every process necessary for the purpose. Specific gravity.—The specific gravities of alloys of aluminium and copper are,—3 per cent. of aluminium, 8:601; 4 per cent., 8:369; 10 per cent., 7:689. At the Elswick Works, Captain Noble, R. A. goodfrand tracking are consistent and specific and sp R.A., confirmed previous experiments on the capability of aluminium bronze to resist longitudinal and transverse fracture; and, in addition to this, he ascer-tained that its position to withstand compression stood halfway between that of the finest steel and the best iron. The bronze containing 10 parts of aluminium and 90 of copper affords an alloy endowed with the greatest strength, malleability, and ductility. The colour of the copper is affected by a very trifling addition of the other constituent, and the alloy gradually improves in those valuable qualities just mentioned until the proportions given above are reached. After this—that is to say when more than 10 per cent. of aluminium enters into the composition of the bronze -the alloy gradually becomes weaker and less malleable, and at length so brittle that it is easily pounded in a mortar.—Ref. Ure's Dict. of Arts, Manufactures, and Mines, 6th edition.

BRONZE-PAINT, which in Commerce is generally called gold-paint, is a preparation of gold-coloured bronze-powder and turpentine. The turnentine employed in the macufacture of bronze-paint is mixed with lime to neutralize an acid reaction which it usually has

BRONZE-POWDERS are made from an alloy of copper and zinc, in varying proportions, according to the shade required. In the preparation of the green bronze there is an admixture of verdigris. The alloy, after being laminated into very thin leaves and carefully unnealed, is levigated into an impalpable powder with fine oil. Mr. Brandeis, a large American manufacturer of bronze-powders, states that bronze, or, more correctly, metallic powders resembling gold dust, were invented, in 1648, by a monk at Furth, in Bavaria, named Theophrastus Allis Bombergensis. He took the scraps, or cuttings, of the metallic leaves, then known as "Dutch leaf," and ground them with then known as "Dutch leat," and ground them when honey. This roughly-made bronze-powder was used for ornamenting parchments, capital letters in bibles, choral books, &c. Until the American firm of Messra. Brandeis took up the manufacture of bronze-powders by a patent scientific process, and on a large scale, the markets of the world were principally supplied from Furth, in Bavaria, where the manufacture was from Furth, in Bavaria, where the innaulacture was carried on in the primitive way in which its inventor had left it. When it is remembered that bronze-powders are largely used in bronzing iron and tin ware, in japanning, as well as in the embellishment of ornamental works in leather, oil-cloth, wood, paper, &c., we may observe why the demand for them is so large and so steadily increasing. "There are four sorts of Dutch leaf:—Common leaf, soft and of reddish cast, is composed of 25 to 30 per cent. of zinc to 75 "There are four

## Bronzite

or 70 per cent. of copper. French leaf contains more zinc, is harder, less ductile, and has a purer yellow colour. Florence leaf has a larger proportion of zinc, and is a greenish god-colour. Lastly, White leaf is composed of tin. The more zinc these alloys contain, the more zinc these alloys contain, somposed of tin. The more zinc these shows contain, the harder, the more brittle, and more difficult are they to work into perfect leaves. The manner of beating is similar to the mode of producing gold leaves. The acrupa, buttings, and fragments of these leaves are the materials for the German bronze. leaves are the materials for the German bronze-powders: first brushed through a sieve and ground with gum-water on marble slabs for six hours, the gum washed out, the powders sorted, dried, and a coating of pure grease given to make them appear more brilliant, and to protect them from oxidatios. Varieties of colour, such as orange, &c., are produced by a film of sub-oxide upon the surface of the particles."—Ure's Dict. of Arts, 4c. An analysis of the best European bronze-powders has been given by Dr. Konig in the following table:—

	Copper per Cent.	Zine per Cent.	Iron per Cent.	Tin per Cent.
1. Light yellow	52:38	16-69	0-16	0
2. Gold-yellow	84:50	15:30	0.07	0
yellow	90.60	9.61	0.20	0
4. Copper-bronze orange 5. Copper-red high shade	98:93	0.73	0.08	0
of purple colour	99-90	0.00	trace	0
6. Purple-violet	98.23	0.2	0.30	trace
7. Light green	84.32	15.02	0.02	trace
grey	0-00	2.30	0.56	97:46

BRONZITE, bron'-zite, a variety of dialtage occurring in serpentine and greenstone. It is found in dark green foliated masses, with a pearly metallic lustre resembling bronze; whence its name. Chemically it is a silicate of magnesia, containing small portions of lime, protoxide of iron, manganese, alumina, and water.

BROOKITE, brook'-ite, oxide of titanium, crystallizing in thin hair-brown masses; found on Snowdon and in Dauphiny.

BROOM. (See Crrisus.)

BROOM-RAPE. (See OROBANCHACER.)

BROSIMUM, bra'-si-mum (Gr. brosimos, estable), in Bot., a gen. of plauts belonging to the nat. ord. Artocarpacea, or Bread-fruit family. The species B. ntile, sometimes called Galactodendron utile, is the celebrated pale de vaca, or cow-tree, of South America. It yields a milky juice, said to be almost as nutritious as milk from the cow. From the bark of B. namagna strong fibres are obtained, which are much used in Panama for making sail-cloth and ropes.

BROTHER, bruth'er (Lat. Frater: Ger. bruder), is a term denoting the relationship between a male and a male or female born of the same father and mother. male or female born of the same father and mother. When the relationship is only by one of the parents, the term half-brother, or brother of the half blood, is frequently used. A brother-german is a brother both by the father's and mother's side; a brother-uterine, only by the mother's side. A foster-brother is one suckled by the same nurse, but not born of the same parents. A brother-in-law is a relationship by marriage,—the brother of one's wife, or the husband of one's sister. In Scripture, the term brother is used in a wider sense, as in the case of Abraham and Lot. one's sister. In Scripture, the term brother is used in a wider sense, as in the case of Abraham and Lot, Jacob and Laban, &c. It is customary for kings to style each other brother; and persons in the same profession, as judges, bishops, priests, &c., not unfrequently do so. The primitive Christians called each other brothers, and monks of the same convent usually adopt the same phraseology. Certain classes of monks were particularly called Brothers; as the monks of St. Dominic, Presching Brothers; those of St. Francis, Minor Brothers. (See Bekthern) Lay brothers were an inferior class of monks, not in holy orders, but bound by monastic rules, and usually employed as ser-

### Brucite

vants in the monasteries. They were sometimes called outer brothers. In the Middle Age writers, brother sometimes denotes a comes, or governor of a previous. In a more general sense, brother or brethres is used for mankind in general; all the human race being descended from the same parents.

BROUSSONETIA, broc-so-net ti-d (in honour of M. BROUSSONETIA, 6706-80-ne-si-a (in noneur on man Broussonet, a French naturalist and traveller), in Both, a gen. of plants belonging to the nat. ord. Moracce. There is but one species, B. papyrifera, the paper nulberry, the bark of which is used in Chira and Japan as paper material, and in the South-See Islands. for making a kind of cloth. The plant forms a small tree, with soft, brittle, woolly branches, and large, hairy, rough leaves, either heart-shaped and undivided, or cut into deep irregular lobes. It is not uncommon in British shrubberies. BROWN COAL, broun-kole, a name used for lignite, in contradistinction to fine coal, which is black. (See

LIGNITE.)

BROWNIE, brou'-ne, the name of a kind of fairy formerly believed in in the Hebrides and North of Scotland. He was an obliging sort of elf, that used to come into houses by night, and perform lastily any piece of work that might remain to be done. At one time every family of importance believed that they had a special brownie, and they gave him offerings of the various products of the place. Thus some, when they churned their milk, or brewed, poured some of the milk or wort through the hole of a stone called the brownie's stone. The brownie of Scotland bore a very striking resemblance to the Robin Goodfellow of England.

BROWNING, broun'-ing (Ang.-Sax.), a process by which the barrels of muskets and rifles are partially which the parties of makers and rines are partiesly oxidized and sulphur nized, and so prevented from being easily rusted. The barrel being brightened and cleaned thoroughly from oil, a mixture of nitric acid, chloride of iron, sal namoniac, and sulphate of copper, is laid on, and allowed to remain several hours. The process is repeated several times, and the barrel is cleaned

ultimately with alkaline water, and polished.

Browners, bround ists, a sect of Christians which arose in England towards the end of the 16th century, and took their name from their founder, Robert Brown, a man of some learning, but of an impetuous and fiery temper. He began to inveigh against the ceremonies of the Church of England in 1580, and zealously diffused his sentiments by preaching from Place to place, principally in the county of Norfolk. Being greatly opposed, he left England with a congregation which he had collected, and settled at Middleburg, in Zealand; but, quarrelling with his flock, he, three years afterwards, left them, and returned to England. He again itinerated through the country, and preached with considerable success; but he afterwards conformed to the established church, and obwards conformed to the established church, and obtained the rectory of Oundle. His followers, however, continued to increase, so that Sir Walter Raleigh, in 1692, estimated their number at upwards of 20,000, exclusive of women and children. They were treated with great rigour, and several of them were executed in the reign of Elizabeth. Many fied to Holland, where several churches were established; as in Amsterdam, Rotterdam, and Levden. This sect subsequently dam, Rotterdam, and Levden. This sect subsequently merged in the Independents, of whom Mr. Robinson, pastor of the Brownist church at Leyden, is regarded as the real founder. The Brownists differed from the Episcopalians mainly regarding ecclesiastical order and discipline, for their theological opinions were generally conformable to the Articles of the Church. Their doctrines and church government very much resemble those of the English Independents of the

resemble those of the English Independents of the present day. (See INDEPENDENTS.)

BRUCIA, or BRUCINE, bru'-se-d, an alkaloid coourring in large quantities in conjunction with strychnis in the strychnes nur vomica. It is less marked in its 
properties than strychnis, which it closely resembles, 
It crystallizes in colourlesss transparent rhombio 
prisms, which are insoluble in other. Its poisonous 
properties are less active than those of strychnis. By 
the action of nitric sold of brucia, compounds are abproperties are less active than those of stryohnis. By the action of nitric acid of brucia, compounds are abtained which render it probable that methyl enters into the composition of this alkaloid. (See STRYGENIA)

BRUCITE, bru-site, a fibrous hydrate of magnesia,

#### Brumaire

converting in allky greyich or bluish-white masses. A name given to choodrodite or chrysolite.

Barnann, bru-massy (Fr. brume, 10g), the name given to the second mouth of the year in the French resolutionary calender. It commenced on the 23rd of October and ended on the 21st of November, thus comprising thirty days. It received its name from the forsitat usually prevail about this time. The 18th of Brumpire, VIII. year (9th of November, 1799), is cele-

brated for the overthrow of the Directory and the stabilishment of the sway of Napoleon.

Burning of the sway of Napoleon.

Lauring of the sway of Napoleon.

anat. ord. of directledonous plants in the sub-class control for the sway of Napoleon.

They are small heath-like shruhs, found Colpeifore. They are small heath-like shrubs, found at the Cape of Good Hope and in Madaguscar. Their

properties and uses are unknown.

Bernorian Streem of Medicine, bru-no'-ni-da,
was founded by Dr. John Brown, a Scottish physician,
was founded towards the end of last century. His
system is explained at large in his "Elementa Medicina," published in 1780. It found numerous supporters, and gave rise to much opposition. According to him, the characteristics of life are sensation and motion; the capability of being affected by external powers is termed excitability; the agents are simil, or excitage powers; the result is excitement. When the affinable act upon the excitability with a sufficient stimule act upon the excitainty with a sufficient degree of power, there is a pleasant sensation of health; when they raise the excitement above this point, or depress it below it, disease takes place; and when the stimule cease to act, or the system to feel their power, death ensues. The stimuli are of two external and internal; the external being heat, light, air, food, medicines; the internal, the functions of the body, muscular exertion, powers of the mind. Exotement is life, and the body has an uncessing tendency to dissolution, which is only opposed by the societant application of excitement. All stimuli, by a sting upon the excitability, tend to exhaust it. Our asting upon the excitability, tend to exhaust it. Our our excitability,-of wasting it by day in labour and enjoyment, of recruiting it by day in labour and enjoyment, of recruiting it by night by the abstraction of all stimulating powers. All diseases are of two kinds—astkenic, or diseases of weakness, or debility; and sthenic, or diseases of excess of strength. His mode of treatment of treatment of the strength of the state of the strength of the strength. mode of treating diseases, therefore, had for its object morely the increasing or diminishing of excitement, without regard to their particular symptoms. The doctrine, in its original form, may be considered as exploded; but more recently a sect has arisen, principally in Rally, who profess a modification of the Brunomian system, and who are known as Modern Brunomians. They advocate what is known as the contra-stimulant mode of treatment of disease.

BEDEAFWICK GREEN, brand-wik, a pigment con-sisting of oxychloride of copper, formed by exposing supper dippings to the action of hydrochloric acid, or astrong solution of sal-ammoniac, in the open air.

BRUSHES, BRUSHMAKING, brush'-es (Fr. brosses; ex. bursten), instruments used for painting or for removing dirt by light rubbing, from floors, furniture, &c.
They are generally made of hair, bristles, or whalebors,
and are divided into two chases,—simple and compound
Simple brushes are composed of a single tult, and
compound brushes consist of several tufts inserted in c handle. Painters brushes are examples of the after kinds of simple brushes are known by the name of pencils, and are made of camel or sable-hair, in-acreed in quills of different sizes. When coarser and stronger material is used, they are generally mounted in the tabes, and known by the name of tools, the larger these being bound round sticks with string or copper Linds being bound round sticks with string or copper wire. After these come whitewash brushes, which consist of two or more large tufts fixed side by side on a disk handle, and secured firmly with string or wire. Company of the same of the same that a number of tufts are inserted into holes perforated at regular distances in making brushes to the description, the workman takes a tuft of a size corresponding to the hole; holding it compactly tocorresponding to the hole; holding it compactly to-getter, he dies it into a mixture of melted pitch and bellow, and then binds that end firmly with a piece of atrong thread called a thrum. He then dips the bound and take the pitch and tallow again, and inserts it with

## Bryonia

a peculiar twist into one of the holes. The pitel mixture sets rapidly, and the tuff is very firmly secured Hearth-brushes, bunister-brushes, and other bouse brooms, are all made in this manner; the lighte kind of dusting-brushes are also made equilarly. most important substances used in making brushes are bogs' bristles. In the brushes above mentioned the bristles are used the full length, but when brushes are wanted for hard rubbing or sambling, they are est short. In these short-baired brushes the tuite are generally inserted by the druwn method. In this process the back of the brush is bored in a similar manner to that described, after which a smaller bores manner to that described, after which a smaller beyer is used, and the perforation carried right through the stock. The brushmaker then takes a smaller number of bristles than will fill the hole, and attaches their ends to a fine wire, which is passed through the hole in the stock and drawn tight up to a knot. He then passes this wire, which is very flexible, through another hole, and forms another knot, and so on till a row is completed, when he cuts off the ends with a strong pair of shears furnished with a gange, which regulates pair of shears furnished with a gauge, which regulates the length of the tuft. The back of the brush is then covered with a thin piece of wood as a veneer. Toothbrushes and ivory brushes are often made with silver wire which is left visible; and sometimes the tufts are held in their places by a process called trepanning, The ends of the wires in trepanned work are secured the ends of the wires in trepanned work are secured laterally. For making soft brushes, such as hatbrushes, goal's-hair, and other kinds of hair, are much used. The process of drawing in the coarser description of brushmaking is performed by men, but women are largely employed in the manufacture of fancy brushes, and the selecting and cleaning of the bristles. The value of the brushes and brooms exported from this country in 1956 was £37,041.

BEUSH-TURKEY (Tolegalla Lathomi). called also the wattled tailegalla, inhabits New South Wales, from Cape Horu to Moreton Bay. It is about the size of a common turkey three parts grown. The whole of the upper surface is of a blackish-brown, the feathers of the chest edged with silvery grey. The skin of the head and neck is of a deep red, and the neck is ornamented with a bright yellow wattle. The most curious circumstance connected with the brush-turkey is, that it does not, like other birds, hatch its eggs by sitting on them, but collects together an immense heap of decaying vegetable matter as a depository for its eggs, and trusts to the heat evolved during the process of decomposition for the development of its young. This heap is gradually collected by the bird for several weeks previous to the period of laying, and is sometimes so large as to contain two or three curtleads. Savs Mr. Gould: "The mode in which the materials composing these mounds are accumulated is singular; the bird never uses its beak, but, grasping a quantity in its foot, throws it backwards to one common centre; thus clearing the surface of the ground completely for a considerable distance round. The heap being accumulated, and time allowed for a sufficient heat to be engendered, the eggs are deposited, not side by side, as is ordinarily the case, but planted at the distance of nine or twelve inches from each other, and buried, at nearly an arm's depth, perfectly upright, with the large end upwards. They are covered up as they are laid, and allowed to remain till hatched. I have been credibly informed, both by natives and settlers living near their hounts, that it is not unusual to obtain no bushel of eggs at one time from a single heap; and as

they are delicious cating, they are eagerly sought after."

BRUTE, brute (Lat. brutus), a term applied to those animals which act by instinct only, in order to distinguish them from men, who act by reason. It is synonymous with the word beast.

BRYACKE, bry'-ai-se-e (ir. brac, I sprout), in Bot., Urn-mosses, a sub-ord, of the Moss fame, distinguished by the sporangium dehiscing transversely, either from the separation of the operculum or in an irregular manuer. (See Musci.)

BRYGAUSS, brig'mate (Gr. brucke, I grind my testh), in Med., is the grinding of the teeth, or that grashing and chattering of the teeth which takes place in egelepsy and other convulsive disorders.

BRYONIA, bri-o'-ne-a (Gr. brue, I sprout), in Bet . e

## Brypm

gen. of plants belonging to the nat. ord. Cocurbitaces. The most interesting species is B. dioloa, the red-berried bryony, or wild vine, as indigenous perennial, growing in hedges and thickets, and blossoming during the month of May. The flowers are yellowish-white, with green streaks, and are discious; that is, the male and ismale flowers are borne by distinct plants. The stems are put forth annually, and climb by means of tendrils. The root is large, white, and is cold by her balists under the names of white bryony and mandrake-root. (For the true mandrake, see MANDRAGORA) The root contains a peculiar bitter principle, termed Bryonia. It is u violent emetic and purgative, and is highly poisonous, giving rise to symptoms much resembling those of cholers. It is stated to be frequently used by quack doctors in the country, and is employed as a topical doctors in the country, and is employed as a topical application to bruises. B. alba, Americana, and Afria, have similar properties.

BRYUM, brit-was, in Bot., a gen. of Mosses in the sub-ord. Bryaces. The species are very numerous, and many of them are natives of Britain. Their stems are short, and their leaves form tiny rosettes, from the

centre of which the fruit-stalks spring.

Buses, but-size, a South-African plant, found growing in the Maravi country by Dr. Livingstone. It affords a remarkably strong fibre, which is used by the natives for stringing beads upon. The botanical characters and relations of the plant have not yet been ascertained.

BUBBLE, bub'-bl (Du. bobbel), a small vescicle or bladder of water, or any other fluid inflated with air or

BURBLE, is a cant name for a strong bubbling male liquor.

BUBBLES, a name given to fraudulent or unsubstantial commercial projects, which hold out prospects of speedy gain, for the purpose of enriching the originators at the expense of ignorant and sanguine speculators. The term is generally applied to those schemes in which the funds are raised by the sale of shares, or by a subscription to a transferable stock. The name was first given to undertakings of this kind at the time of the South-Sea project. By this notorious scheme, capital to the amount of three hundred millions was involved. The Bubble Act (6 Geo, I. c. 15) entirely prohibited, the formation of companies by gambling in transferable stocks, or by the sale of shares, stating that they had "manifestly tended to the common grievance prejudice, and inconvenience of great numbers of his Majesty's subjects in their trade and commerce." The Bubble Act was repeated by the stat. 6 Geo. IV. c. 91; and the projectors of bubble companies are now only punishable, when they can be found guilty of fraud and conspiracy, at common law.

Buno, beer bo (Gr. boulon, the groin), in Med., de-notes a swelling of a lymphatic gland, particularly those of the groin or armpit. It may arise from mere irritation or some local disorder, in which case the bube is termed sympathetic; or it may arise from the absorption of some irritating matter, or from con-stitutional causes.

BUBONOCKLE, in Med., is a term applied to inguinal hernia. (See HERNIA.)

Brocat, buk'-kil (int. bucca, the check), in Med. denotes of or belonging to the check; as, the buccal arters, which is a branch of the internal maxillary; the buccal glandules, small mucous glands, or follicles, situated within the cheek, under its lining membrane.

BUCCANELES, but uners, a class of pirates who infested the coasts of the West Indies and South America in the 16th and 17th centuries. The term is The term is derived from a Caribbee word, bonean, which was applied to the flesh of cattle cured in a particular manner. The natives taught the process to the colonists, and the French, who adopted the word, formed from it the verb boscaner, and the noun boscanier; whence our term buccaneer. The buccaneers owed their origin to term buccaneer. The buccaneers owed their origin to the jealousy of the Spaniards, who refused to allow any other nation to settle or trade in that part of the world. Enterprising adventurers of other countries worm. Enterprising accenturers of other countries were naturally averse to submit to this, and the cruelties that were practised against those that dared to make their appearance there, were such that the adventurers formed themselves, about 15% into an association, not merely for natural defence, but for car-

#### Buchanites

rving out aggressive operations against the f fact were principally English and Prench. n a state of constant warfare, carrying on ho independently of peace or war at hom frequent descents on the coasts, pundering stroying the weaker towns and settlements. their principal settlement for some time on th of St. Kitts, and afterwards on Tortuga, near St. mingo; and, when not engaged in traffic with Indians, or in excursions against the Spaniards principal occupation was the hunting of wild ea which they made boucan. At a later period, man them became logwood-cutters in the Bay of Camp The Spaniards, however, continued to harass and most der them wherever they were to be found, and the enmity between them, instead of subsiding, only became more intense. By degrees, many men of good birth joined them, usually under an assumed name. The history of these men abounds in deeds of daring and high valour, but is also marked by deeds of reing crucity. Among the great leaders whose names figure in the history of buccaneering are the Franchman Monthars, called the "Exterminator;" Peter of Dieppe, called "Peter the Great;" and Henry Morgan, a Welshman, afterwards knighted by Charles II. and made deputy-governor of Jamaica. A high s and made deputy-governor of Jamaica. A high states of honour seems to have existed among them, and it is said that holts, locks, and all kinds of fastenings, were prohibited among them, as implying a suspicion of their honour. In 1670 a treaty of peace was consciuded between England and Spain, which provided for the extinction of the buccauser warfare, but with little success. The war between France and Britsin, after the accession of William III. in 1698, affected what treaty could not accomplish by causive a disacafter the accession of William III. in 1688, affected what treaty could not accomplish, by causing a dissociation of the ancient alliance, and a war between the two parties. The treaty of Ryawick, in 1897, and the accession of a French Bourbon prince to the throne of Spain four years later, brought about the final suppression of the buccaneers. After their appression, a race of pirates, of a much more dangerous and desperate character, arose, and for a number of years preyed upon the commerce of all nations, until stilling the state of the state length they were hunted down and exterminated. The name given to the buccaneers by the French is generally filbustiers, apparently a corruption of the English word freebooters, and whence the Americans have their term Filbusters—Ref. Burney's History of the Buccaneers; Dampier's Foyagas; and the Narrotices of Water, Ringrove, and Sharp.

Buccinaton, buk-si-nai-tor (Lat. buccina, a trumpet), in Anat, is a muscle of the cheek, so called from history brought much into play by trumpeters.

being brought much into play by trumpeters.

BUCCINUM. (See WHELE.)
BUCCINUM. (See WHELE.)
BUCCINUM, bu-sen'-taur (Gr. bons, an ox, and
entauros, a centaur), was the name of the state galley an ox, and of the republic of Venice, in which the doges annually, on Ascension-day, "married the Adriatic." This our

RUCKSTAME.

tom is traced to a naval victory gained on Assensionday, 1177, by Doge Sebastiano Ziani over the emperor Frederick Barbarosas. The pope presented Ziani with a gold ring as a sign that on that day the Advistic had been subjugated to Venice, "as a spouse to her husband." Annually, on Ascension-day, the degs, with great pomp and ceremony, and with a numerous attendance, proceeded in the Bucentaur, and deopped a gold ring into the Advistic, with these words. "We wed thee with this ring, in token of our true and perpetual sovereignty." When the French took Venice, what is said to have been the ancient Bucentaur was what is said to have been the ancient Bucestaur

BUOMANITES, buk'-da-ifee, the name of a sect of rall-

gious fanstics which sprang up in the west of Scotland shout the year 1783. The iounder of the sect was a Mrs. Elizabeth Buchan, the wife of a potter in Glasgow, who, from slight sherrations, at length gave herself out to be the woman spoken of in Bevelstion with the sained over to her behief the Rev. Mr. White, minister of a Belief congregation in Irvine, and many of the inhabitants of Irvine were induced to become followers. White was represented as the man child born of the woman. They went from house to house explaining the Surptures, praying, and testifying that the end of the world was at hand, and that it was the dusy of every Christian to abandon the concerns of time, and to prepare for the reception of Christ. Such proceedings led to popular turnilts, and she and many of her followers were expelled from the town in May, 1783. They found a settlement at Clesetown in May, 1784. They found a settlement at Close-burn, Dumfriesshire, where they remained for some time living in daily expectation of being translated to heaven; and on one occasion their leader conducted them to the top of a hill, from which they were going to be taken up to heaven; but, after waiting for a con-siderable time, they had to return disappointed. After siderable time, they had to return disappointed. After this many of them left the society, and Mrs. Buchan herself died in 1792; but there still remained a few survivors, the last of whom died in 1846.

BUCSU LEAVES. (See Barosma.)

BUCS, but (Sax. bucca), the male of the fallow deer. A buck is called a fawn in his first year; a

pricket in his second; a sorel in his third; a sore in his fourth; a buck of the first head in his fifth; and a great buck in his sixth. The female of the buck is termed a doe. The term buck is also applied to the male of the goat, sheep, rabbit, and hure. The male of the red deer is termed a stag, or hart, and never called

a buck. (See DEER, STAG.)

Bucknown, buk'-hound, a kind of dog formerly very common in England, but comparatively rare now. It was used exclusively for buck-hunting, and closely resembles the staghound (which see). Many varieties

of bounds, beside the buckhound, are now used for deerhunting.

BUCKER, buk-ing (Ang.-Sax.), in Min., is a term applied to crushing ore by hand on a plate called a bucking-plate, by means of a flat-headed hammer.

BUCKLER, buk-ler (Fr. boucier), a shield or weapout of defence worn on the left arm. It was of dif-

ferent sizes, and made of different materials. It was attached to the arm by two straps, one of which passed over the fleshy

BUCKLER

part of the forearm below elbow, and the other was grasp-ed in the haud. The Roman spearmen wore bucklers about four feet long by two in breadth, slightly curved in form, behind which they crouched before or after hurling the javelin: it WAS made

wood, strengthened with leather and metal plates and bosses. In medieval times the buckler was a generally round or oval. The Scotch target was a mokler of bull's-hide, ornamented with a rim, boss, ad stads of metal: it was used to catch and turn away the blow of a sword or lance, and always formed part of the equipment of a Highlander.

Bycsaan, but a nignander.

Bycsaan, but am (Fr. bongram), a sort of strong, coarse lines cloth, gummed, calandered, and dyed several colours. It is employed in drapery, garments, &c., when they are required to be kept stiff in a particular form, and also for making wrappers to cover beles of merchandise.

Browsers, buk-kin, a name given to a strong, twilled woollen cloth, generally used for making trousers. It is highly milled to the width of twenty-seven inches, and the pile or map is so finished as to show the taxture through it. It has doubtless obtained its name from its strength and toughness, and its resem-blance in these respects to leather made from the skin of a buck.

BUCKTHORN. (See RHAMNUS.)

BUCKTROEN. (See RHAMNUS.)
BUCKWHEAT. (See RHAMNUS.)
BUCKWHEAT. (See FAGOFIEUR.)
BUCKULCS, Jew-kol-lks (Gr. houkelika), properlymeans pastoral, pertaining to cattle, and is the name
given to a species of poetry which was common among
the ancient Greeks, but has been little cultivated by
the moderns. It represented rural affairs, and the life
and manners of shepherds. The prema of Theooritus,
Bion, and Moschus, and the Ecloques of Virgil, are of
this class. The metre employed is the hexameter, or
heroic; but the lines flow more easily here than in
epic poetry.

epic poetry.

Bro, bud (Du. bot.), in Bot., the organized rudiment of a branch or a flower. Buds which produce leaves, and have the power of extending into branches, are called leaf-bude; while those which produce flowers only, and are ordinarily destitute of this power of extension. receive the distinctive appellation of flower-buds. Theoretically considered, however, a flower-bud is merely a modified leaf-bud; for all the different parts of a flower may be regarded as altered leaves. A leaf-bud usually originates in the axil of a previously-formed leaf, the terminal bud of a branch being no exception to this rule. Every leaf has one or more of these organs in its axil, either in a rudimentary or perfect Whether lateral or terminal, each bud consists at first of a minute conical cellular mass, which com-municates with the cellular tissue of the stem or branch. Around this, spiral and other vessels and wood-cells are soon developed, and these are also connected with similar parts of the wood. Outside all, in a cellular substance, which ultimately becomes the bark, the rudimentary leaves are developed. By the growth of these parts, a little conical body is produced, which, under favourable circumstances, develops into a branch resembling in every respect the parent axis. In temperate and cold climates, the buds, which remain dormant during the winter, are generally covered with modified leaves, called scales. These protective organs are usually of a hardened texture; sometimes they are covered with a resinous secretion, as in the borsechestnut and several species of poplar; and sometime. they have a dense coating of soft hairs, or down, as in some of the willows. Buds thus protected are said to be saily. In the buds of tropical regions, and those of herbaceous plants which are never exposed to the cold of winter, such protective organs would be useless, and are accordingly absent. These buds are distinguished as naked. In a few instances, even buds of perennial plants growing it cold climates are maked, like those of tropical plants; such is the case with the alder, and with the buckthorn. Within the leaf-bud the future leaves are often very curiously folded, or rolled up, and the different positions which they assume are highly characteristic of different kinds of plants. The arrangement of the leaves in the bud must not, therefore, be overlooked by the practical botanist. (See VERNATION.) A leaf-bud may be removed when young from one plant and grafted upon another, by the process of badding, so as to continue to form its different parts: indeed, in some instances, it may even be made to grow in the soil immediately after removal. In certain cases, moreover, leaf-buds are naturally detached during the life of the parent, so as to form independent plants, and thus propagate the species.
On this account they have been called fixed embryos by some botanists. They are, in fact, embryo plants fixed to the axis, capable of sending stems and leaves in an upward direction, and woody fibres, which may be considered as roots, downwards. A tree may second ingly, be said to consist of a series of leaf-buds attached to a common axis, or trunk. In ordinary trees, in to a common axis, or irunk. In ordinary trees, in which there is provision made for the formation of numerous lateral leaf-buds, any injury done to a few branches is easily repaired; but in palms, which only form central leaf-buds, and have no provision for a lateral formation of them, any injury inflicted on the bud in the axis is extremely likely to have a prejudicial effect on the future life of the plant. Leaf-buds are sometimes extra-axillary; that is to say, they are occasionally developed in other positions besides: the axil of leaves. Such buds are somed admirity. the axil of leaves. Such buds are termed adventitions

or abnormet. The woody nodules, called embryo-buds, seen in the bark of the beach, alm, and other trees, are looked upon as partially-developed abnormal buds, in which the woody matter has been hardened by the in which the woody matter has been hardened by the pressure of the surrounding tissue. The nodules sometimes form knots on the surface of the stem; at other times they appear as large excrescences; and in some cases twigs and leaves are produced by them. Adventitious buds are produced naturally on the edges of certain leaves, and on the surfaces of others. These are capable of forming independent plants. Similar bads may be made to appear on the leaves of General, Oldering, and Achimens he wanning various care. Ends may be made to appear on the loaves of Genera, Glazinia, and Achimenes, by wounding various parts of them, and placing them in moist soil: this is the method often pursued by gardeners in their propagation. Flower-buds, like lest-buds, are ordinarily axillary, being produced in the axil of floral leaves or bracts. They cannot be used for budding, for they always die when removed from the parent stem. (See LEAP, FLOWER BULE.)

BUDDINGS, bud'-dizm, a religious system which prevails over a great part of Asia, and is said to have a greater number of adherents than any other religious system among mankind, amounting, according to some goographers, to four hundred millions, or about a third part of the human race. The system is said to have originated in India, about 600 years before the Chris-tian era; but in the land of its birth almost all traces of it have now disappeared. It is the prevailing religion, however, of the inhabitants of the high table-land north of the Himalayas to Siberia, of China, Japan, India beyond the Ganges, Ceylon, and several islands of the Indian archipelago. The founder of the system is said to have been a prince of the name of Siddhartha, son of Suddhodana, king of Kapalavastu, which was somewhere on the confines of Nepaul. He is called by numerous names, but the principal, that of Buddhs, is the wise or suligitated does not seem to have i.e. the wise or colightened, does not seem to have been given to him till after he appeared as a teacher of been given to him till after he appeared as a teacher of religion. In China, Buddiha has been corrupted into Pu-ta and Fo. He is said to have been equally distinguished for great beauty of person and high mental endowments. He early gave evidence of a serious and contemptative disposition, and in order to drive away this, his father surrounded him with all the pleasures of a gay and luxurious court. At the age of twenty he married a charming princess, by whom he had two children, a son and a daughter. Earnest thoughts of the depreciate and misery of human life. however, conthe depravity and misery of human life, however, continue to engage his attention, and he conceives the idea of retiring from society and living in solitude; guards are set over him to prevent his escape; but he tallength succeeds, and takes up his abode on the banks of a river called Arnasara, or Narasara. He was now about thirty years of age, and he remained therefor six years, spending his time in devout meditations. He would, it is said, remain for weeks plunged in deep abstraction, attempting to solve the mysteries of life, death, sin, goodness, wisdom, and such-like.

At length he is enlightened, and comes forth as a religious teacher of others. He first appears at Warnashi (Benares), to propound his new doctrines; and for upwards of forty years he continued to preach his system, traversing a great part of northern India, combating the Brahmins, and making numerous converts. He died in the eightieth year of his age, after making lived to see his doctrine spread all over India. For several centuries Buddhism seems to have continued to flourish in that country, and to have been tolerated by the Brahmins. At length, it seems to have contributed a long-continued persecution, which ultimately had the effect of entirely expelling it from the country where it had originated. What was the cause or the nature of these persecutions is turknown; but the ast traces of the system disappear about the 11th or 12th century; but by this time it had taken firm root in other parts, where it still continues to flourish. Numerous remains of Buddhist temples are scattered over India; and, during the period of persecution, when they were driven from the cities, they retired among the hills of the west, and there constructed stands are seasing the period of persecution, when they were driven from the cities, they retired over India; and, during the period of persecution, when they were driven from the cities, they retired over India; and, during the period of persecution, when they were driven from the cities, they retired over India; and, during the period of persecution, when they were driven from the cities, they retired over India; and, during the period of persecution, when they were drived and period of the containing water in which the ore is washed.

Buddied (Ang.-Sax.), in Min., a trough or blants belonging to the nat. ord. Serophularinovez over India; and, during the period of persecution, when they were drived in the containing water in which the ore is washed.

Burdley (Indiana and many there flower flower ing strubs, and the banding-knife has a point like a lancet, and the handle generally terminates in a thin invertible to be the other flower ing strubs. The budding-knife has a point like a lancet, and the handle generally terminates in a thin invertible to be decised for their graph of the other flower flower flower fruits in general; also for rose and many other flower fruits in gen verts. He died in the eightieth year of his age, after having lived to see his doctrine spread all over India. For several centuries Buddhism seems to have continued to flourish in that country, and to have been tolerated by the Brahmins. At length, it seems to have endured a long-continued persecution, which ultimately had the effect of entirely expelling it from the country where it had originated. What was the cause or the nature of these persecutions is unknown; but the sast traces of the system disappear about the 11th or 12th century; but by this time it had taken firm root in other parts, where it still continues to flourish. Numerous remains of Buddhist temules are anothered

the almost complete absence of dogmas or ritual is, or rather was,—for it has been much corrupted other creeds, an essentially moral system. Its objective other creece, an essentially moral system.

was to teach man how to attain to a pure and holy life in the case of Buddha admits and names a number of the Brahman cal gods, but he sets the Supreme Intelligence above them. The ritual or worship is extremely simple, consisting in offering flowers and perfume, the tepcat-ing of sacred formulas, and the singing of brains. The temples contain only an image of Buddha and a Dagoba, temples contain only an image of Buddha and a Dagoba; or shrine containing his relies. There are no priests or clergy properly so called, but only an order of monks, who have given themselves to a life of sanctity, and who are generally very numerous. They are obliged to live in celibacy; but they may retire from their order if they desire it, and are then permitted to marry. The four sublime verifies, or axioms, upon which the system of Buddhism is built, are—1, that there exists pain; 2, that the cause of pain is desire, are the attemption of the soul towards extrain objects. or the attachment of the soul towards certain objects; or the attachment of the soul towards certain objects;
3. that pain can be ended by Nirvana; and 4, the
way that leads to Nirvana. By the practice of six
transcendant perfections,—alms, morals, science, energy, patience, charity, a man might hope to arrive
at the state of Nirvana,—repose or annihilation. Existence is viewed as a curse rather than a blessing; and the endless transmigrations through other beings that had to be endured, were causes of suffering; and hence the highest object of desire was to be delivered from the necessity of being born again. There are trom the necessity of noing born again. Large are two words precepts of universal obligation; viz., not to kill, not to steal, not to commit adultery, not to list and not to be drunken. There are others for those entering upon a religious life. Ref. Manual of Buddhism, by R. S. Hardy; Introduction à l'Histoire du

sim, by R. S. Hardy; Introduction & l'Histoire du Buddhism Indien, by Burnout; Le Bouddh et ea Religion, by Saint-Hilbire; Edinburgh Review, April, 1862. BUDDING, bud-ing (from Du. bot, a bud), in Hort, a peculiar mode of grafting, in which a leaf-bud is used instead of a young twig or scion. The bud to be employed is cut out of the branch along with a small portion of the bark and young wood, and the woody part is then carefully separated. Two incisions are made in the bark of the stock intended to receive the bud, so as to form the letter T; the bark is raised on oud, so as to form the letter T; the bark is raised on both sides of the longitudinal cut, and the bud, with its shield of bark, is inserted in such a way that the upper edge of the shield joins exactly to the transverse cut in the bark of the stock. The leaf in the axil of which the bud grew is cut off, and the newly-inserted bud is for a while held in its place by strands of bass matting. If the bud is sufficiently matured, and if the bark at-If the bud is sumerency matures, and it are bud, at tached to it is properly fitted to that of the stock, the operation is almost sure to be successful. This is by far the most common method of budding. It is generally distinguished as shield-budding. Another method, raily distinguished as sneed-budding. Another method, called scallop-budding, consists in removing entirely a thin slip of bark from the stock, and fitting into the wound a similar slip bearing the bud. The proper time for budding is a little after midsummer, when the bud is perfectly formed. The process is particularly well adapted for trees which are apt to exude gum

## Bude Light

Buds Laure, buds, a very bright light, rivalling in brilliancy the electric and lime lights, made by arging a current of pure oxygen through the flame of an Argand gas-jet. It derives its name from the village of Buds, in Carawall, where it was first used by its

RUDGET, bud-jet (Fr. bougette), a bag or little sack, such as may be easily carried. It comprises also the contents of the bag or such, and hence has come to denote a stock or store of anything; as a budget of inventions. In parliamentary language, the budget is the financial statement laid annually by the chanreaction of the exchequer before parliament, of the esti-mated public income and expenditure for the follow-ing year, commencing on the 5th April, mentioning what taxes it is proposed to repeal, reduce, or aug-ment, and what new ones are to be imposed. In his speech on the occasion, the chancellor reviews the financial condition of the country, comparing the income and expenditure of the previous year with those of preceding years, justifying the changes that are proposed to be made, and estimating their probable effects. The statement of the chancellor is always looked forward to with great interest, and frequently gives rise to much excitement, as involving important

BUDNEANS, bud-ne'-due, in Eccl. Hist., a sect that arose in Poland towards the close of the 16th century, and took their name from their founder, Simon Bud-neus. They denied the divinity of Christ, and refused to worship him, adopting, also, many wild vagaries. Their founder was afterwards admitted into the communion of the Socinians, and his followers seem to have dispersed.

BUFF, or BUFFY COAT, buff, in Med., is a light yellow riscid substance, which is formed on the surface of blood drawn in certain states of disease.

BUFFALO, buf'-fa-to (Ital. and Span. bufalo; Bos bubulus).—This animal differs from the bison in having no hump on the back, and only a small dewlap on the no aump on the user, and only a man down, to breast. Besides this it carries no shock of hair about its neck and shoulders. They generally live in flocks of about a hundred, and affect marshy regions, both on account of the coarse but luxuriant vegetation there to be found, as well as the opportunity for a "mud bath, of which the buffalo is remarkably fond. The way he indulges this ugly predilection is singular: throwing himself flat upon his side in the mire, he shuffles round and round, the soil yielding to his immense weight the exudation of any moisture it may contain, morter covering him to his very eyes. When be emerges and has basked awhile in the sun, he looks like some hideous elack-baked clay image. This manouver, however, is not without purpose. Among the rank vegetation, and in the air, swarm millions of stinging Sies, and until the buffalo's mud coat peels off through long wear, he is as impregnable to their attacks as the slay image he represents. The buffalo is one among the very few animals who manifest no fear at the approach of the tiger; indeed, sportsmen concur that unless a tiger be full-grown and in possession of all his strength, will not venture to attack the bull buffalo. Should the tiger, made desperate by hunger, attack a herd of buffalces, his fate is certain. The whole herd will band segainst the common fee, and, assailing him with hoofs and horus, rend his striped hide to gory ribands, and trample him maimed and crushed into the mire.

Russes, buf fer, in Engin, a rod with an enlarged and attached to a spiral spring of great strength, fixed to the striking parts of locomotives and railway cariges, in order to diminish the shocks arising from

any sudden movement or stoppage.

Surveys, bog'-fai (Fr.), anciently denoted a small partment separated from the rest of a room, and need for containing china, glass-ware, &c. The name mass accountaining canal, glassware, ac. In the mine mass afterwards applied to a outpoard or set of shelves, which was used for a like purpose, but which has now been superseded by the modern sideboard. Buffet, or buffet stool, was also applied to a small wooden stool

American ozen and cows. They are dressed with oil

#### Buhr-stone

in the same manner as chamois leather. Buff teather is very plinble, and not liable to crack or rat. It is used for making bandolins, belts, pouches, gloves, and other articles.

Burra, Burra, boof fo, a term applied by the Italians to an octor and singer who takes the humorous and Indicrous parts in their operas. The epithet is also applied to the pieces themselves; as opera suffe, a comic opera

BUFFORT, buf-font', a projecting covering of gauze or linen for a lady's breast, an fashion in and after the year a period when English ladies' costume was very ungraceful. The buffont entirely concealed the neck and hosom, and stuck out from beneath the chin like the breast of a pigeon. It was generally accompanied by some other ugly articles of costume which were invented at that time. The figure in the illustration wears the buffont, the cumbrous head-dress, and the little frilled jacket, of that period. The buffont was worn in Paris as late as 1788.

BUFFORT.

Burroon, but foon' (Fr. bouffon; Ital. buffo), a low jester, a man who amuses others by rough tricks, antic gestures, broad jokes, and such-like. The name is said gestures, broad jokes, and such like. The name is said to be derived from the barbarous Latin word buff. (cheeked), a name given to those who appeared on the stage with their cheeks puffed up to receive blows on them, and thus to excite the laughter of the spectators. In Italy the term is not always used in a contemptuous sense: there there are two sorts of buffouns,—the buffo cautante, who has frequently an important part to play, requiring considerable musical talent, and the bidlo comico, whose part consists more in acting. In England the name was sometimes applied to those persons who were employed as fools at court or at the

tables of great men.

Bug, bay (probably Welsh bag). — This tiresome insect is too well known to need a devotion of space to its description. It is commonly asserted, though with what degree of truth it is hard to say, that before the year 1670 the insect in question was unknown in England, and that it was imported from America with the timber that country furnished for the rebuilding of London after its destruction by the great fire. Its blood-sucking propensitier, and the disgusting smell it emits when excited, are in these days no wonder amongst us. The female bug deposits her eggs at the beginning of summer: they are small, white, and of an oval shape, each being fixed to a hair-like giutinous stalk, ready to adhere to anything it touches.

Bugus, bu'-gl (Ang. Nor.), formerly a brass instru-ment without any keys, used only by hunters and for military purposes; within the last few years, however, it has been so much improved by the addition of six keys, that it now is of the greatest service both in solo and concerted music, and is very commonly found in orchestral and military bands. The bagle, when played with taste, forms a delightful accompaniment for the piauoforte, and possesses the advantage over most other horus, of a methodical fingering, by which the true tones can be produced without so much recourse to the car as would otherwise be necessary.

Bugloss. (See Archusa.)

BUHL-WORK, or, more properly, BOULE-WORK, bool, generally used as a footstool.

Bury Learnes, but lead or contracted from but for the lides of lead of leaster made from the hides of Boule, a famous French cabinetimeker of the time of lafficions, or from the salted and dried hides of South Louis XIV.

BURE-, BURER-, or BURE-STONE. boor a name often

#### Building

# Building en Pice

to certain quartrose rocks the worked surfaces of which possess the property of catting or grinding. They are used principally as millistones. The best kinds are creamy white, with a granular and somewhat cellular texture, and are obtained in the tertiary form-cities of the Paris basin and the surrounding district. They are cut into wedge-shaped parallelopipeds called anes, which are bound together with iron hoops to

form large milistones.

form large muscores.

Building, bit-ding (Sax. byldan, to build).—By this term is understood the art of putting together certain materials, such as stones, bricks, timbers, slates, &c., wrought into various necessary forms, for the purpose of constructing dwelling-houses and other editices required for public or private purposes. In building, the builder practically carries out the ideas of the architeet, who contrives the plan of the required edifice, that it may be well fitted for the purpose for which it is intended in every respect, and be suitable for the locality in which it may happen to he placed. architect also furnishes the builder with working drawings of the various elevations of the edifice and vertical sections of different parts, the form of the roof, ground-plans of the several floors, plans of the staircases, and drawings in detail of ornamental portions of the exterior and interior, drawn exactly to a certain scale. He also gives the builder specifications of the materials to be employed in the construction of the building, and the manner and form in which the materisls are to be applied; and to do this, it is necessary that the architect should have a practical as well as theoretical knowledge of the strength and durability of the different materials used in building, particularly timber, and the forms and arrangement in which their capability to resist pressure and tension can be employed to the greatest advantage. The builder, having carefully examined the plans and specifications provided by the architect, enters into an agreement to perform the work required for a certain sum, under-taking it by "contract," as it is termed; or he binds himself to execute it at certain valuations for different parts of the work; that is to say, at so much per perch for walling in stone; so much per rod for brickwork; so much per square for rooting, flooring, and paving; so much per foot for woodwork of different kinds, &c. charging for the work by what is called a "schedule of prices;" in which case it is measured after its completion by persons appointed by the architect to value what the builder has done, and it is paid for according to their valuation. During the progress of the building, the work is superintended by a "clerk of the a competent person acting under the architect's orders, to see that the builder faithfully follows the specifications; using good materials, and applying good workmanship, through the agency of mechanics in his employ who are well skilled in the different branches of constructive building. In building, particularly with reference to dwelling houses, great attention should be paid to the following points :- The situation should be such as will insure freedom from damp, and protection from north-easterly and easterly winds; the principal apartments should have, if possible, a western or southern aspect; the ground on which the house is built should be of a nature to secure a good supply of water, and a sufficient fall for drainage; and the posi-tion of the doors and windows should be regulated in a manner relculated to secure freedom from draughts manner rescansed to secure precion from arranging said emoky chimneys, which is to be obtained by ascertaining the direction of the winds to which the dwelling will be chiefly exposed. The method of construction adopted in the various component parts of buildings of a public and private nature, will be found on reference to their respective headings, as well as notices of the various styles of architecture and ornsmental details, and plans resorted to in building with mental debats, and plans resorted to in building with different kinds of material. (See the articles Auch, Architecture, Arrival, (See the articles Auch, Brown, Brickwork, Building en Pisk, Building-Grone, Carbenter, Cellar, Chimney, Coping, Derige, Architectural, Done, Door, Fireproof Buildings, Fide, Foundation, Gallery, House, Johnson, Tarway, Marshey, Massager, Massager, Massager, Parsware, Parsware ERBS, FIDER, FOUNDATION, GARDINEY, PAINTENS, PAPER-TAMBUNGS, PLASTERING, ROOF, RUSTICATED WORK, SCAPPOLBING, STATE, STATECASE, STUCCO, SMOKE, SEWER, TIMBER, TILING, WALL-PLATE, WINDOW, &c.,

&c.) The large contractors, as the late Mr. T. Cabits, Messus; Lucae & Kell, the contractors for the great Exhibition building of 1982, and others of equal adob-rity, employ machinery worked by steam power in the manufacture of various ports of buildings, which to to insure great accuracy of fitting when the part which tond are put together; and, indeed, there are certain particularly in the metropolitan districts, who emp thomselves entirely in the manufacture of parts parts of a house, such as doors, windows, &c., by my chinery, which greatly facilitates the operations of the builder, particularly if they he on a small scale, cost him considerably less than they would if he had purchased the material and employed artisans to execute the material and employed artisans are material artisans are material and employed artisans are material and employed artisans are material artisans are ma cute the required work. The more machinery can be brought into operation, the chapper buildings can be raised; and hence the advantage and greatly increased rate of profit that accrue to contractors whose espital rate of profit that accrue to contractors whose cepitas; enables them to exect machinery to accomplish the construction of different parts of their work. It is said that progress in the art of building, in different localities, is always controlled by the material that can be most readily procured in the neighbourhood, said that greater architectural beauty, convenience, and elegance, are attained and shown in cities where stone, the contractor of the property of the contractor of the profit of the contractor of the contractor of the profit of the contractor of the contractor of the profit of the contractor of the co that can be easily worked, can be had in the immediate vicinity. The truth of this is certainly evinced in the numerous magnificent structures in stone that are to be seen at Rome, St. Petersburg, Paris, Vienna, Brussels, Edinburgh, Glasgow, New York, and other European and American cities; but, in the present day, it has been shown that much can be effected in brickwork in every way, as exemplified in the buildings lately erected in that material in and around London, Manchester, and Liverpool; and a still higher degree of perfection will be obtained when more attention is paid to the production of coloured or polychrome bricks, and the brickwork is so arranged as to obtain the juxtaposition of broader masses of colour, that will present a more pleasing effect of contrast or harmony than can be found in the intersection of walls of one colour by single stretching-courses of another, few and far between, or the formation of the straight or camlar between, or the formation of the straight or cambered arches above doors and windows by alternative wedges of colour, just the thickness of a brick. The most beautiful and pleasing buildings in the world may be produced in brickwork, if the dressings, coins, and ornamental details, be formed of clay, coloured and moulded to suit their position in the building, and this architect be animated by the taste and feeling of an artist in consume the coloured materials to require the coloured and the coloured materials to require the coloured and the coloured materials to require the coloured and t artist in grouping his coloured materials together.

BUILDING ACT FOR LONDON AND ITS NERGEROUS-HOOD. (See METBOPOLITAN BUILDING ACT.)

BUILDING EN PISE, a method of building walls with compressed earth, which has been practised in France for a long period of time, perticularly in the southern part of the country, about Lyons. Walls built or this plan somewhat resemble the old "cob" walls of mud and straw, of which barns, cottages, and garden-walls were sometimes made in agricultural districts in various parts of England; but they are more durable, more finished in appearance, and better calculated to withstead the weather from the matter durable. which the weather, from the method adopted in raising them. The foundations of the walls are made of stone or brick, and are raised a short distance above the level of the ground. Earth is then procured, which is neither too hight from containing too much sand, nor too heavy from the presence of clay in gre sand, nor too neavy from the presence of casy in green quantities, but which consists of rich soil, sufficiently moist, with a little fine gravel in it. This is rammed into a solid mass on the top of the foundation, being kept in the proper shape and position by a sort of mould formed of two boards, that are held apart by iron bolts and screws to the extent required for the thickness of the wall, and are removed as soon as the portion of wall hatween them is completed. The wall portion of wall between them is completed. portion of wall between them is completed. The waith is made in courses a few inches in depth, and the earth is added in smul quantities at a time, that every portion of the wall may be well bestes together. The face of the well on the exterior, and the interior as well, if required, is thus formed:—the earth that is next the boards forming the mould, is taken out, and a space left, about an inch or two in depth, between the board and the main part of the wall, which is filled.

## Building Leases

with a facing composition formed of three parts of earth and one part of lime, mixed together with water like morter, but showed to dry, and reduced to powder before it is rammed in. It hardens and forms a solid coating, which keeps the core of the wall free from moisture. To avoid settlement from shrinking of material, all the bond timbers and pieces of wood placed in the walls are made as thin as possible, and the openings for doorways and windows are formed by inserting frames of thick plants in the required posi-tions and resuming the activities. meeting frames of thick planks in the required posi-tions, and ramning the earth closely against them as against the sides of the moulds. The walls may be whitewested or coloured, and smoothed by a wooden instrument used by plasterers, which gives them a very next appearance. They are very durable if protected from damp as much as possible, as walls of this descrip-tion have stood in France for more than a hundred and appears a sound as when they were first years, and appear as sound as when they were first built; and the durability of the cob-wall, without any external facing, is well known. As the material costs nothing but the expense of bringing it to the spot where it is to be used, the cost of buildings constructed in this way is very low in comparison with that of houses of stone and brick. Mr. Robert Salmon, of Moburn, Bedfordshire, who has creeted many buildings in this way, found that the cost of a square yard of wall built en pise was only one fourth of that of a square yard of brickwork in that locality, if finished with facing composition on one side only, and onethird, if fluished on both sides.—Ref. Transactions of the Society of Arts, vol. xxvii.; English Cyclopadia— Arts and Sciences.

BUILDING LEASES. (See LEASE.)

BUILDING SOCIETIES are in the nature of a jointstock company, established to raise a subscription-fund by advances, from which the members shall be compled to build or purchase dwelling-houses, or to purchase land; such advances being secured to the society by mortgage of the premises so built or purchased. They are established upon the basis of rules provided, to be sanctioned under the provisions of the acts relating to friendly societies, and they are made subject in general to those acts. The members become shareholders by The members become shareholders by paying an entrance-fee and binding themselves to make a periodical subscription, for the most part, by monthly a periodical succerption, for the most part, by monthly payments. The non-payment subjects the member to a fine limited by the rules. The members are either investers or borrowers. When the fund ruised is large enough to let out, loans are made to the borrowers, and so from time to time, as subscriptions are paid in, fresh advances are made. The borrowers thus anticipate what they would otherwise receive on the termination of the society. In general, the money borrowed cannot be repaid in one sum, but only by the periodical subscriptions, the mortgage remaining a security for the payment thereof, and of the flues incurred through default of, or irregularity in, paying such subscriptions.

The loan and use of the money advanced being upon the
principle of compound interest, it follows that the term of the mortgage by repayment of the money, and, con-sequently, the duration of the company, must be limited to a given number of years. This term varies in different societies in proportion as the amount of subscriptions is greater or smaller, and generally ranges from ten to fourteen years. A society may, however, become permanent by the successive issuing of fresh shares; but the interest in and liability under, each share must terminate when the time arrives for the investing member to be paid the sum fixed by the rules in respect of it, or when the borrowing member has fully paid up his subscriptions. If the security taken by the society be good and ample, the invester would obtain his money at the expiration of the calculated time; but it frequently happens that losses arise on the calculated of the property under the mortgage, and the term between to the investers is postponed, and their interinguated benefit much reduced. If the society be rainable, it must follow, that as the time runs out, une of the investers must be paid off. The persons to be paid are determined by lot, or some other mode provided by the rules. The rules are settled and approved by a barrister, who is appointed to revise the rules of, and register, all benefit and riendly societies.

There are many kinds of stone

nd register, all benefit and friendly societies.

BULLIMIA, bul-i'-mi-i (Gr. bons, an or, and times, sed for building purposes, differing greatly in quality bunger), in Med., denotes an insatir us graving for

#### Bulimia

and durability. That which at present appears to be considered the best for buildings in which the stone is required to be wrought by the mallet and chisel into various ornamental forms, and retains, its marpness after exposure to the weather, is a magnesian limestone, a stone which consists of earboarde of limeatone, which was used for the new Houses of Par-A stone much used for the dressings and coins of buildings, as well as many other ornamental purposes, is an colitic limestone of a rich cream-colour; known as Bath-stone or freestone, which is quarried in the vicinity of Bath and the Isle of Portland. Dartmoor, in Devenshire, and in Scotland, in the neighbourhood of Aberdeen and to the north of that town, granite is obtained, which is hard and difficult to work, but which is well calculated for paving stresss and building bridges, and for the basements of public buildings, from its great durability. Sandstones of various kinds, such as the old and new red sandstone, green-stone, and basalt, are also used, and the lime-stone found at Purbeck, in Dorsetshire, on the coast of Devonshire, and in other parts of Great Britain, which furnishes handsome slabs of black, red, and grey marble, veined with white, which are cut and polished for mantelpieces, &c. The chemical composition of the various kinds of building-stone, the causes which lead to their deem, and the vergesses well is prefert lead to their decay, and the processes used to protect them from the action of the weather, will be found under their respective headings. BUKKUM-WOOD. (See Creatrinia.)

Bull, bulb (Lat. bulbus), in Bot., a shortened stem or branch, usually subterranean, bearing on its surface a number of fleshy scales, which are modified leaves. It is only found in monocotyledenous plants, and is seen in the byacinth, bly, and onton. The built may be looked upon as a subterranean leaf-bud, arising from a shortened axis. From its centre an herbaceous stem arises, and from the subterranean axis new bulbs, or cloves, as they are cailed, are produced. Every new

bulb is formed in the axil of a scale, like a bud (which see); sometimes it remains attached to the parent bulb, and sends up an axis and leaves; at other times, it is detached in the course of growth, and forms an inde-pendent plant. The new bulls feed on the parent one, and uitimately cause its complete absorption. The scales are generally thickened by the deposition of nutritive matters, in-In the onion, equill, and leck, these scales are covered externally by thin membrancus coats or tunics; hence the bulbs are said to be tunicated. When the membranous coats are ab-

BULD OF

When the membranous coars are absent, the build is said to be maked or acaly, as in the white high. The colid rounded underground stem, called by botanists a corm, is commonly regarded as a bulb. (See Court.)
Bellius, or Bullius, half-bils, in Bot., small conical or rounded bodies produced in the axil of the leaves of some monocotyledonous plants, and which are of the nature of build. They can be readily disare of the nature of buibs. They can be readily distinguished from ordinary leaf-bads by their fleshy character. They are easily detached from the perent stem, and, when placed in favourable circumstances, they produce new individuals. They may be seen in Lilium bulbiferum, Dentaria bulbifera (corai-wort), and

Bulgarian Language, bulgai'-ri-da, is a branch of the Sclavonic, and is divided into two dislects,—the old and new Bulgarian. The old Bulgarian is the richest in inflections, and its literature is the oldest of any of the Sclavonic tongues. The new Bulgarian has arisen since the destruction of the kingdom in 1392, when the language came to be mixed with those of neighbouring nations, particularly of Wallachia and Albania. The new Bulgarian can scarcely be said to possess any literature; but it has a large collection of ropular acres.

#### Bulkhoad

food. Persons labouring under this disease feel all the effects of hunger, even when the stomach is full and the stories that are told of the quantities of food consumed in such cases are scarcely credible. The real consumed in such cases are scarcely creatible. The resi-nature of this disease is very imperfectly known. In some cases, the health appears to be otherwise good; but usually bulimis is a concomitant of other dis-cases. Its consequences are learness, pulmonary fevers, consumption, dropsy. Sometimes there exists are extended and residually appears to the system has been much exhausted, or from a certain condition of the stomach, which causes it to digest the food with too great rapidity; but these do not indicate disease,

but only excessive appetite.

Bukuran, bulk-hed, in Mar., a name given to certain partitions built up in several parts of a should between two decks, either lengthways or across, to form and separate the various apartments. Some of those which are built across the ship are remarkably strong. Those which inclose the magazine are of oak plank, and rabbeted, as are those of the spirituous-liquor room. Others in the hold are generally oak plank, cyphered, to keep the gravel or dirt of the sulfast from getting into the storerooms, or into the well to damage the pumps. Water-tight bulkheads well to damage the pumps. Water-tight bulkheads are iron partitions running athwart the hold. By means of these, the body of the vessel is divided into several water-tight divisions. Hence, if the vessel is leaking in one part, the rest may remain dry till the injury is repaired. Nearly all large vessels are now injury is repaired. Nearly all large vessels are now made with these buikheads. The Great Bustern has ten of them, reaching nearly to the level of the upper deck.

BULL, bull, a term applied on the Stock Exchange to those brokers who contract to buy any quantity of stock or shares, without having the intention or ability to pay for them, and who are, therefore, obliged to sell again, either at a profit or a loss, before the time at which they have contracted to take it. It is the consents of lear facility.

it. It is the opposite of bear (which see).

Bull (Du. bulle), in Zool., the male of the Bos or hoving gen. of quadrupeds, of which the cow is the

female.

Bult, in Lit., denotes an equivocal expression, a blunder, a contradiction, errors to which the Irish are particularly liable. "I confess it is what the English call a bull, in the expression, though the sense be

manifest enough. — Pope.

Bull, Golden, is the name given to an edict or imperial constitution granted by the emperor Charles IV., and regarded as the Magoa Charta of the German empire. It received its name from the scal attached to it being in a gold box, and was granted by the emperor at an imperial diet held at Nürnberg in 1356. This bull regulated the form and ceremony in the This bull regulated the form and ceredinally in the election of emperors, determined the number of electors, with their functions, rights, privileges, &c., all of which were previously undetermined. It comprised thirty articles, and the original is still preserved at Frankfort-on-the-Maine.

BULL, PARIL (Lat. bulla, a seal), is a written letter issued from the Roman chancery by order of the pope, and scaled with lead. The bull is, strictly speaking, only the seal or pendent lead, which alone gives the document its authority. It is impressed on the one side with the heads of St. Peter and St. Paul, and on the other with the name of the pope and the year of his pontificate. Bulls are written in old Gothic characters, upon stout and coarse parchment, and are granted for the consecration of bishops, the promotion to benefices, celebration of jubilees, &c. They are either bulls of grace or bulls of justice; in the former the seal is attached by a cord of silk, in the latter by a cord of hemp. Bulls are distinguished from brieves both in form and character. The latter are more abcool in form and cuaracter. The latter are more abbreviated in their form, are written upon flue parchiment in Boman characters, are issued by the apostolic secretary, and sealed with red wax. Brieves are of the same authority as bulls, though issuing from different same suttoons as ourself and the government, both being equally re-departments of the government, both being equally re-garded as acts of the pope. The Bull in Carna Domini is a particular bull which was read every year on the day of the Lord's Supper, or Maundy-Thursday, in the presence of the pope, containing excommunications and anothernes sgainst heretics and all who disturbs

### Bull-dog

oppose, or disobey the Roman pontiff. After the bull was read, the pope three down a burning torch in the public place, to denote the thunder of this austhema. The reading of this bull was discontinued by Chement XIV. In the Middle Ages bulls were also used by kings and emperors in great affairs of state. In affairs of the greatest importance, golden bulls were employed; silver, leaden, and waxen ones being made use of in matters of less moment.

BULLA (Lat. bulla, a round boss or stud), a small round ornament made of gold or silver, worn by the children of the ancient Roman nobility. The bulls was work until they arrived at the age of fourteen, and was placed upon the neck or breast. It was a distinctive

mark of free birth.

Bulla, a genus of molluscous animals with univalve shells, whose general characteristics are,—that the shell is sub-oval, that the aperture is oblong and shell is all the conselled. The smooth, and that one cud is a little convoluted. The animal breathes by gills, but has no respiratory tube, and consequently the margin of the aperture of the shell is entire. Most of this genus, especially of the larger sizes, are furnished with an organ succely re-

larger sizes, are furnished with an organ exactly resembling the gizzard of a fowl, and which they appear to use for the purpose of masticating their food.

BULLAGE, bull-laise, the English name of a kind of plum, the Prunus institute of botanists. (See PRUNES.)

BULL-BATTING, bull-built-ing (Du. bulls, bull; Gotts, bull; Gotts, bulls, bull; Gotts, bull; Gotts, bulls, bulls, bull; Gotts, bull; Gotts, bulls, bull; Gotts, bulls, bull; Gotts, bulls, bull; Gotts, bull; Gotts, bulls, bull; Gotts, bull; bull; Gotts, bull; bull; Gotts, bull; bull; Gotts, bull; bull

beitan, to bait), is the harbarous sport of bailing bulls with dogs. The animal was usually tied to a stake, with the points of his horns muffled, and then attacked by the dogs, who tore him to death for the amasement of the spectators. It is said to have been introduced as an amusement into England about the year 1209.

BULL-DOG, bull'-dog (Canis molosous), a variety of the dog, remarkable for its broad, short muzzle. It is generally looked upon as an essentially English dog; hut there is a doubt as to whether it has not existed as a definite race since the time of the Romans, or whether it is not a recently-formed variety. of mastiff. It is smaller than the mastiff, and has a massive head; the forehead sinks between the eyes, and the nose-line rises again at a considerable angle; the lower jaw projects in a remarkable manuer beyond the upper, continually showing the teeth; the lips are thick and pendulous, the neck strong and thick,

BULL-DOG.

and the legs short. The projection of the under-jaw and the livid redness of its eyes give the buil-dog a fierce and forbidding aspect, often heightened by a designing leer, which seems natural to the animal. The strength and courage of bull-dogs are proverbial. They will attack any animal, utterly regardless of its strength and size. They were formerly much used for bull-builing; since the abolition of which sport, the breed has decreased in numbers. One of these dogs will seize an ox by the nose, and, with apparent case, hold him still, or throw him on his side, as he is ordered by his masters When trained for the purpose, they fight very savagely with one another; and in cert in of the mining and manufacturing districts of

#### Bullet

England this sport is still carried on. On growing old, the bull-dog becomes very vicious and dangerous, often inflicting severe bites on the slightest provocation. The bull-terrier is a cross between the dog and the terrier. It is, if possible, more closs than the bull-dog itself. It is, if possible, more fero-

BULLET, bull-let (Fr. boulet), the name given to sany kind of leaden missile which is discharged from a ride, fowling-piece, or pistol. Prior to the introduc-tion of the various kinds of modern rifles with barrels furnished with numerous spiral grooves, the bullet a molten state into a mould, the diameter corresponded with the calibre of the weapon for which it was intended. For the old rifle with two deep grooves in the interior of the barrel, the bullet was carronaded with a projecting rib, and was made by casting the lead in a grooved mould. Builets of all chapes are now made by compression, a method inflartely superior to that of casting them, as there can be no irregular cavity or air-hole in any bullet formed by pressure, a thing which would seriously affect the fight of any projectile, and cause it to fall wide of the mark, on account of the eccentricity of motion that would be imparted to it, arising from the vavity causing it to be lighter on one side than on the other. The first attempt to form bullets by compression was made about 1840, by Mr. Napier, whose machine was adopted by the government and used at Woodwich. It by the government and used at Woodwien. It was worked by steam power. Strips of lead, first subjected to heavy pressure under rollers to produce condensation of the metal, were passed under a machine by which they were pressed into longths resembling. strings of nearly round pieces of lead. These lengths vere then passed between hemispherical dies, or plungers, which closed on each piece with great force; when the dies receded from each other, the bullets were ejected by springs, which noted on plugs in the dies, and came out in the form of a perfect sphere, connected, however, by a small piece of metal, which was removed by the action of a punch worked by a treadle, under which the bullets passed in succession. The old round bullets were from 14 to 20 to the pound; the calibre of the weapons for which they were in-tended varying from 60 or \$ of an inch to 68 or \$7 of an inch. The spherical bullet is now entirely superseded by conical clongated projectiles of various forms, the principal of which is that used for the Enfield-Pritchett rifle. This bullet is spherical at one end and remonet the. I'ms others spherical at one and and hollow at the other, which is next the powder when the musket is loaded. The cavity is in the form of a fruncated cone, and extends into the bullet pretty nearly half its length. A little boxwood plug, about half the depth of the cavity in height, is fitted into the end of the bullet, leaving a small hollow space in its interior between the ping and the bottom of the cavity. When the powder explodes, this wooden ping is driven deeper into the cavity, and causes the lead, which presents the form of a tolerably thin ring at the flat presents the strike of expand and fit tightly into the grooves of the rifle, by which windage is prevented, and the securate flight of the missile towards the mark insured. There are many kinds of bullets of the concal form, with numerous contrivances for obtaining expansion at the moment of discharge, but they are too numerous to mention here in detail. The principal are those made by Minie, Delvigne, Norton, Robins, Beaufoy, Manton, and Greener. The Minió bullet somewhat rescribes the Enfield; but it is pointed at the upper ends and of being hemispherical, and the cavity at the legislation of the being hemispherical, and the cavity at the legislation of the lower end, which answers the same purpose as the wooden plug in the Enfield bullet, causing the expension of the lead into the grooves of the rife. Mr. Greener was the first who made a bullet on this principle, in 1833, and received a reward of £1,000 premapes, in 1853, and received a reward of £1,000 from government for his invention in 1857. The Enfeld bullets are made by compression in machines which draw the lead into them in the form of rods and ent them into pieces of the proper length, which are stamped or pressed into the required form by four steel dies with which each machine is furnished. Each machine will furn out about 190 bullets nos miner. ent them into pieces of the proper length, which are black predominates; the back is achievey; breast and stamped or pressed into the required form by four belly dusky red; wings and tail black; upper tail steel dies with which each machine is furnished. Each machine will turn out about 120 bullets per minute. resembles the male, except that her colours are less

#### Bullanen

The boxwood pluge, which are inserted into the cavities of these projectiles, are also cut by machinery.—Ref. Busk's Rifle and does to use it, and Mandbook to Hythe; Coles's Catechiem of Masketry.

Bullett's, bull-let-in, is a term derived from the French, where it originally signified a ballot used in

elections; and hence a small piece of paper on which one gave his vote. Alterwards it came to signify an official report, giving an account of the actual con-dition of some important affair intended for the information of the public. When kings or other persons of high rank are dangerously ill, daily bulletins are issued by the physicians respecting the state of the patient. In time of war, builetins are issued by the generals, announcing the state of an army or the result of a battle. This practice became common in the French army under the first Napoleon.

BULLET-THEE, or BULLY-THEE, a tree supposed to belong to the gen. Mimusops, in the nat. ord. Supotaceae. It is a native of Guiana, and much valued for its tim-ber, which is hard and durable. It yields a delicious

fruit about the size of a cherry.

BULL-FIGHTS, or combats between men and bulls, are a very ancient kind of amusement, and were common in Greece several centuries before the Christian era. In Rome, under the emperors, they were also common, and alterwards they became popular in many of the other countries of Europe. At present Spain is the only country in Europe where they are still held. In Madrid and all the larger towns of Spain bull-fights In Madrid and an the mager common open are frequent. In Madrid the season lasts from April to November, during which time bull-lights take place at least once a week. The combats are held in a large at least once a week. The combats are held in a large amphitheatre called the Plaza de toros, open at the top, and with sents rising one above another round the circle, and capable of accommodating from 10,000 to 12,000 spectators. The area is divided into an outer and an inner circle, separated from each other by a strong fence, the latter being the place where the combats take place, the former affording shelter to the men on foot when hard pressed by the bull, in order to which there are a series of openings in the fence just large enough to allow a man to pass through. The actors on the arena are the bull, usually of the fierce Andalusian or Castilian breed; the picadores, or combutants on horseback; the landeritleros, who are armed with sharp goods with coloured attenuers; the childs, who weat very bright-coloured clocks; and the matador, who dispatches the buil. The contest begins with the picadores, who are each around with a lance, and mounted usually on a very worthless horse. Their object is to wound the bull with the lance, and then to avoid his onset. The horse is frequently gored in the encounter, and when a picador is closely pressed, the banderilleros and chulos rush in and withdraw the bull's attention by pricking him with their darks and waving their clouks. When the bull begins to flag, the picadores withdraw, and are succeeded by the banderilleros, who are armed with banderillas, or darts, about two feet long, ornamented with a coloured flag. the banderillero sticks into the bull be and the horns when it is preparing to toss him. After a time the third act of the play commences, and the manador enters upon the stage, attended by some chalos as assistants. Over his left arm he has a red mantle, behind which is concealed a sword which he has in his right hand. He awaits the charge of the bull, and, if well skilled, dexterously plunges the sword between the shoulder and the blade, and the animal drops dend at his feet. Twenty minutes is the time usually taken to terminate the contest, and eight or ten bulls are often dispatched in a single day.—Ref. Ford's Handbook of Spain.

BULFINER, bull'finsh (Ang.-Sax.), (Loxia, pyrrhula), a song-bird common to all parts of England
and Europe generally. It is about the size of the common hedge-aperow, but of bulkier build, and rather
more than a third of its length is monopolized by its tail.
The bill is short, strong, and of a blue-black colony.
On the upper part of the head, round the base of the
beak, and forming a chin-shaped patch beneath, jet
black predominates: the back is ash-crey: breast and

## Bull-Frog

distinctly marked, and her under perts are rather russet than red. The builfinch has acquired considerable calebrity from the facility with which it learns to whistle airs. Training builfinches to "pipe" is a mode of making money frequently practised in Germany: considerable pains are requisite. There was one Ger-man bullfinch-teacher, named Lewis de Berg, whose

BULLFINCH.

turds were sold for their weight in gold. "I feed the wrote he; "I give "maller birds with rape-seed." them likewise, at times, a little bruised rice soaked in comary wine, and afterwards dried carefully for use. Though giving the hird a few grains while wet with this

excellent liquor does mighty well, yet it does not do to be constantly practised. — Ref. Beeton's Home Pets.

Bull-Frac (Rana nipicus), the largest of the species Rana, or Frags. It is generally six to eight inches long, exclusive of the feet, and four inches broad. is an inhabitant of North America, particularly of the southern states. At a distance, its voice resembles the lowing of a bull; hence its name. The fore feet of the bull-frog are unwebbed, and have only four toes; but the hind feet, which are long, are webbed very widely. Its colour is a dull olive, marked irregularly with dark stains; the belly, however, is of a pule green colour, thickly spotted. The bull-frog frequents green colour, thesity spotted. The building frequents springs only where the constant running of water has made a deep pool. Scarcely a spring of this description is without a pair of these frogs. When surprised, with a spring or two they leap into their retreat. They prey on young ducks and geese, which they swallow whole; it is also believed that they keep the springs in which the resident and the springs in

which they reside wholesome.

Bullhard, or Miller's-revens, bull-hed (Cattus golio), a small fish, common to our brooks and rivers. It is about four inches long, with a large roundish head, and a capacious mouth, formidably filled with teeth. It is generally found under loose stones at the bed of the stream, and is seemingly so insensible to danger, that, should half a dozen of them be lying together, the invenile angler may capture the whole by continuing to drop in his bait till they are all hooked. The term bullhead is considered to refer to the large size of the head, and the name of miller's-thumb is doubtless applied because of the resemblance of the same part to the thumb of a miller, which, like this fish's head, is smooth, and broad, and rounded, a form produced by a peculiar and constant action of the muscles in the exercise of his occupation. The miller's hand is constantly pisced under the meal-spout, to ascertain the quality of the grinding. The thumb, by a particular movement, spreads the sample over the fingers, and serves as a gange of the value of the produce.—Ref. Yarrell's British Fishes.

BULLION, bull-yon, properly signifies uncoined gold and sliver, or, more strictly, refined gold and sliver in bars or other masses; but in political economy the term is frequently used to denote the precious metals both coined and uncoined. The word is said to be derived from the French billow, base coin, from the currency in France having been much debased by the sings. There are numerous interesting quill be found needed with the subject of bullion, which will be found treated of in different parts offenis work (as Bankino, 1 treated of in different parts of the still an open question CURRENCY, MONKY, &c.). It is still an open question what effect a great increase in the supply of the presions metals would have upon the value of money.

## Bungalow

The great increase in late years of gold, brought in America and Australia, has at least had no percept effect in that respect. At the Bank of Engls all builion of the standard fineness offered for must be bought at the uniform price of 43.474.04 an ounce; at the Mint it is bought at the rate of 43.174.104d; but the seller must wait for payment until the bullion can be converted into money; and hence the former mode of disposing of it is the preferred.

BULL's-EXE, the black or gold mark in the centre

BULL-BYE, the black or gold BRIE in the country of a target. (See TARGET.)

BULL-TROUT, bull'-trout (Salmo Erioz, or Salmo priseus).—This fish, which is often called the Grey Trout in England, and the Sowen in Wales, is nearly allied to the salmon. It generally lives in the sea, but deposits that the country is not as elegant as that its spawn in rivers. Its form is not so elegant as that of the salmon; its head and neck are thicker, and its tail more bulky in proportion. The colour of the male is reddish brown,

and that of the female dark grey; their scales are smaller than those a salmon of of equal size. Anglers look upon the bull-

RULL-TROUT.

trout as ranking next to the salmon as regards sport. It is usually under 15 lbs. weight, but some attain a weight of 20 lbs. The flesh, which is lighter coloured than that of the salmon, is coarser, and has not so delicate a flavour.

BULRUSH, bull'-rush, the popular English name for any large rush-like plant growing in marshes. (See

BULWARK, bull-wurk, in a man-of-war, the bearding above the upper deck fastened to the outside of the timber-heads and stanctions. They protect the men in action from the fire of the enemy. In ordinary vessels they are simply a protection from the waves. and prevent articles from being washed overboard. If a sailing vessel has to be converted into a man-of-war, the bulwarks require to be greatly strengthened. The name of bulwark was formerly applied in mili-tary art to ramparts and bastions.

BUMASTUS, bu-mas'-tus, in Geol., a gen. of Silurian trilobites, remarkable for their oblong-oval or grapelike form. They occur in lerge numbers in the lime-stone of Barr, in Sialfordshire, and on this account are commonly called the "Barr trilobites."

BUMBOAT, bum'-bote, a kind of wherry, used in and about harbours, for carrying provisions for sale to ships lying at a distance from the coast. Bumboats are frequently called shore-boats, to distinguish them from those belonging to the vessels.

Buncu, bunch, in Min., a mass of ore too small and irregular to constitute a vem. When a mine is full of such masses, to the exclusion of regular veius, it is said to be buncky.

Bunganow, bun'-qd-lo, an East-Indian term for a sort of house or villa, with a thatched roof. They are occupied by Europeans, and very in size and accom-modation, according to the fancy or requirements of their owner. They generally consist of a ground-floor,

BUNGALOW.

surrounded by a verandale, but some are of two ste ries. In the principal cities of Bombsy, Madras, and Calentta, the bungalows of the wealther class of Europeans are spacious and nugnificent: the large

#### Bundon

number of demestic servants required by European residents are accommodated in affuoent offices. Public bungalows are for the reception of travellers, and are maintained by government. They are fitted up with rooms, beechambers, bath-rooms, tables, chairs, &c., for the use of which the traveller pays a ruper, that is two shillings, per day. The traveller himself is expected to come provided with food, drink, cooking utensils, bedding, and servants; but, in some of the better sort of hungalows, the khitmutgar supplies those necessary articles. The distance between the public bungalows is usually from twelve to fifteen miles, which is a good Indian day's journey. The introducwhich is a good Indian day's journey. The introduc-tion of railways will most probably effect a conversion in the public bungalow, and make it, in some measure, approximate to the English botel. Military bungalows for the accommodation of soldiers in cantonments,

and are on the same extensive scale as barracks.

Buylon, bun-yun (Gr. bounos, an eminence), in Surg.,
is a painful inflammatory swelling of the foot, most commonly about the root of the great toe. The pressure of tight shoes is usually the exciting cause; and, in order to remedy it, all such pressure upon the part should be avoided. Bleeding by leeches, warm fomen-

tations, or positives, should be resorted to, in order to remove the inflammation. The swelling may sometimes be considerably reduced by caustic.

BUNIUM, bu'-ni-um, in Bot., a gen. of plants belonging to the nat. ord, Umbelliferæ. The species are perennial herbs, with usually taberose and globose roots, square stems, compound leaves, and white flowers. B. flexuosum and bulbocastonum, both growing wild in this country, have edible tubers, which are commonly known as earth-nuts or pig-nuts. B. ferulaceum, a native of Greece, has also edible tubers, which are termed topana.

BUNKUM, bunk-um, is an Americanism, applied to speech delivered merely for the purpose of conciliating popular favour, or gaining popular applause; a species of oratory more commonly to be met with in erica than in most other countries.

Bunt, bunt, a disease of wheat and other grains,

BUNT, ount, a cisease of wheat and other grains, caused by a parasitic fungus. (See Unedo.)

BUNTER, ban-ter (Ger., variegated), in Geol., the term applied by the Germans to the new red sandstone of English geologists, in allusion to its variegated colours. (See Transsic System.)

BUNTING, or BUNTINE, bun-ting, a thin woollen

fabric, of which ships' flags are made.

Bunting (Emberiza), an interesting group of passerine birds, whose chief characteristic is a bill very strong, short, conical, and compressed laterally, but without any tooth or notch; the upper mandible is state palatal end, forming, as a whole, an instrument admirably adapted for breaking the rinds or shells of seeds, and ejecting them without losing any of the kernel. The Common, the Yellow, the Cirl, the Ortolan, the Snow, the Reed, and the Lapland, are the various distinguishing names of the British members of this family. Besides these there are the Painted bunting of South America, and the Yellow-shouldered bunting of the Cape. When the female of this last-mentioned species loses, through age, the faculty of propagating her kind, she throws off her comparatively modest attre, and appears, for the rest of her life, as splendidly plumed as her mate; and so exactly like, that it is simply impossible to tell one from the other without the minutest examination.

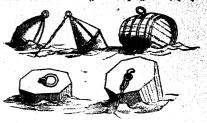

BUNTLINE, bunt'-lines, in Mar., are ropes fastened to cringles (small holes formed in the bolt-ropes of easils) on the boltcome of the square sails, to draw them up to their yards. They are inserted through sertiain blocks above or on the upper portion of the yard; whence, passing downwards on the fore part of the sails, they are secured below to the lower edge, in several places to the bolt-rope.

Brox. bof (Fr. bouts) in Mar. floating bodies con-

Buox, bot (Fr. bonée), in Mar., floating bodies con-tracted of any light buoyant substance, and used either to mark some danger (such as sauds and shoals) or to denote the position of a ship's anchor, &c. They gratitude; but, in addition, it does him the favour of see made in a great variety of shapes. Several of the varning him of the approach of the hunter. cases, as at Spithead, being put in a double line, so us to show the only safe course that a vessel can take. The principal buoys of this kind are under the superintendence of the Trinity House. This corporation has lately adopted a buoy invented by Mr. Harbert, which has the advantage of keeping nearly perpen-

THOUSE.

dicular in all kinds of weather. The bell-buoy is in-geniously arranged, so that any tide or current passing where it is floating moves an under-shot wheel, which rings a bell. It is thus rendered useful in a fog or at

BUOY DUES .- On recount of the importance of buoys in navigation, they are placed under several strict regulations. The Trinity House, under whose ju-risdiction most of the warning and directing buoys are distributed, claims certain dues from all ships entering ports where they are placed. These buoy dues are ports where they are placed. sometimes collected as a tonnage, varying from \$d. to 2d. per ton; sometimes as a payment on entering or leaving the port, and in some cases as a rate on the vessel. Many coasting ressels pay a yearly sum, whatever number of voyages they make. The buoys in the Thames alone bring in an annual rerenue of £11,000 to the corporation of the Trinity House. Buoy, Life. (See Life Buoy.)

BUPRAGA APRICANA, bu-fait-qu, a curious bird, about the size of a full-grown blackbird, distributed throughout Southern Africa, and likewise found in Senegal. Its common habit is to search for its food in the infested hides of wild animals of the ox genus, as well as the rhinoceros, though its vulgar name, rhinoceros-bird, would imply that it was exclusively at-

BUPHAGA APRICANA.

tached to that animal. Its clave are well adapted for holding on securely to its hairy and snimsted pasturage, and its bill is shaped like a pair of wire-drawer's pliers; so that the parasite, although, as is frequently the case so that the parasite, attnough, as in requesting the control buried in the skin, is easily extracted. "If it rendered the rhinoceros no further service than ridding it of these biting pests, it would deserve the saimal's gratitude; but, in addition, it does him the favour of warning him of the approach of the hunter. With its

# Buprestide

slow to understand and take advantage of. Cumming save to uncorretand and take advantage of. Oursming saverts, that when the rhimoseros is saleep and the buphage falls to wake him with its voice, it will peak the inside of his ear, and otherwise ever itself to rouse its thick-headed friend."—Wild Sports of the World.

Burnserns, bu-prestide (Gr.), a gen. of hard-shelled bestles, generally very beautiful in appearance. Green would seem to be their most ordinary colour, but many are of the richest azure, spangled with goldcolors; some are vivid red, and others of a glowing copper has. They are found on the trunks and branches of stees, and, when disturbed, will fall to the ground seemingly without life, and by this means frequently escape. There exist nearly five hundred of this genus, escape. There exist nearly five hundred of this geous, but not more than twenty are commonly met with in

this country.

Bur, Burr, or Barr, ber (Ang.-Sax.), a very small ridge raised on the edges of lines that have been cut on a plate of metal by the action of the graving tool or dry-point. It is generally removed by a tool called a scraper, as it gives a somewhat smeared appearance to impressions taken from the plate if it be allowed to remain. In plates engraved by Rembrandt the bur was not removed, and he managed to take

advantage of it to give additional effect to his etchings.

BURATITE, bu'-rd-file, a hydrated carbonate of copper, containing also sine and lime, occurring in the radiating needles at Chesey in France, and in the

Altai Mountains.

BURBOT, ber'-bat (Gadus lota), an eel-like fish found in many northern English lakes and rivers. It is said however, to attain greatest perfection in the Lake of

Geneva.

BURDEN, ber'-den, in Mus., is that portion of a song which is repeated at the close of every verse or stanza. It is derived from the French bourdon, a drone bass; because the one, like the other, is characterized by the same unchangeable tone, and bears upon the cur with the same monotony. The adoption of a burden with the same monotony. The adoption of a burden in youl music is very ancient, and it is still occasionally introduced with very pleasing effects.

BUEDEN, in Mar., denotes the contents of a vessel,

or the number of tons she will carry.

BURDEN (Ang. Sax. byrden, something borne), in Scots Law, denotes generally any restriction, limitation, or incumbrance, affecting either person or pro-perty. Burdens are thus either personal or real, personal when imposed on a person, real when imposed directly and specifically on heritable property. A proprietor may create a real burden by reservation in parting with lands; but it is essential that it be pro-perly expressed and declared to be a burden on the lands themselves.

BURDENSACK, bur'-den-sak, was a provision in the old law of Scotland, by which a man could not be punished for theft if he took as much meat as he could carry on his back, provided it was to satisfy the gravings of hunger. It is not now recognized in law.

Burry, bu-ro', is a term derived from the French,

and signifying a writing-table or desk; also an office denotes a department of government, and the term bureaueracy is applied to a government, and the term bureaueracy is applied to a government conducted by a series of independent departments, each under the apperintendence of a chief, to whom alone the officials responsible.

BURETTE, bu-ret (Fr.), a vessel used by che-mists for pouring out small and exact quantities of mints for pouring our small and exact quantities on solutions. Burettes are of various shapes, and are generally graduated. They consist essentially of a tube with a fine spout and an opening, which may be closed at pleasure with the thumb.—Ref. C. G. Williams's Chemical Manipulation.

BURGAGE TENURE, ber'-gatj, in Law, is an ancient tenure proper to boroughs, whereby the inhabitants, by custom, hold their lands or tenements of the queen, or other person, by a reat certain. It is, in-deed, only a kind of town-socage, as a common socage, by which other lands are holden, is usually of a rural mature. By the operation of the Enfranchisement

hature. By the operation of the intrancusement, Acts, this species of tenure is gradually diminishing. Bungues, beri-jes (Lat. burgeri). — Burgeses are properly men of trade, or the inhabitants of a borough or walled town; but the term is usually applied to the 377

Burgh Royal

maghtrates of such a town ; as the build and b of Leominster, &c. Before the statute 5 & 6 W; c. 76 (commonly called the Municipal Corpo 6. 26 (commonly cause the municipes approximately deliberated by the four-set for the precion, as there was generally acquired by birth, marriage, or stude, that is, by being born of a freeman, by mythe daughter or widow of a freeman, or by myproximate daughter or widow of a freeman, or by myproximately deliberated by myproximatel ship for seven years within the borough to a treem It might also be obtained by gift or purchase. In boroughs comprised in the act, the definition of a s gess (that is, a burgess entitled to such new rights as the act for the first time confers on these boroughs) is a male person of full age, not an alien, nor having re-ceived within the last twelve months perceival relief. ceived within the last tweive months paroccusar raise; or alms, or pension, or charitable allowance from the charitable trustees of the borough, who, on the last day of August in any year, shall have excupied any house, warehouse, counting-house, or shop, within the borough, during that year and the whole of the two preceding years; and, during such occupation, shall also have been an inhabitant householder within the borough, or within seven miles thereof; and shall, during such time, have been rated in respect of such premises to all rates for relief of the poor, and have paid all such rates, and all borough rates in respect of the all such rates, and all borough rates in respect of this same premises, except those payable for the last six calendar months; and shall be duly enrolled in that year as a burgess on the burgess-roll. Which definition, however, is to be understood as subject to the following rule,—that when the premises come to the party by descent, marriage, settlement, devise, or promotion to any benefice or office, he shall be critical to recken in the occurance and rating of be entitled to reckon in the occupancy and rating of be entitled to recken in the occupancy and rating the former party from whom they were so derived. (See 6 & 7 Wm. IV. c. 104, s. 7; 7 Wm. IV. & I Vect. c. 78, ss. 4 to 9, and 24; and Bosougn in loco. And as to the burgees-roll, see E. v. Hardwich (mayor), 19 Ad. & E. 60; R. v. Eye (mayor), 9 Ad. & E. 670.)
Burgen (Goth. bourge, a city), is a general name given to certain towns and cities in Scotland, and

corresponding to borough (which see) in England. There are royal burghs, burghs of barony, parliamentary

burghs.

burghs.
BURGH ACERS, in Scotland, are acres or small patches
of land lying in the neighbourhood of royal burghs,
usually feued out to, and occupied by burgesses, or
persons resident within the burgh. Statute 1935,
c. 23, concerning runridge lands, exempts burgh acres from division; but the exemption is confined to royal

BURGHERS, ber'-gers, in the ecclesiastical history of Scotland was the name of one of the two bodies into which the Secession church was divided in 1747. which the Secession cutren was divided in 1737. The cause of division was,—Whether it was lawful for seceders to take the burgess eath, professing the established religion and promising to maintain the same. The one party, the Burghers, held that their creed was identical in all material points with that of the established church, and that professing their belief in the one was the same as professing their belief in the other. The Antiburghers, on the other hand, maintained that the oath could only be received in the sense intended by those who administered it. The dispute was carried on with great acrimony for two years, and resulted in a separation. After the separation both sections rapidly increased, and though the animosity was maintained with great bitterness for some time, it began gradually to subside, and at length, in 1820, the two became again united under the name of the United Associate Synod of the Secession Church.
More recently they have become united with several
other bodies into the United Presbyterian Church (which see)

BURGH LAWS (Leges Burgorum), an ancient collection of laws relating to burghs in Scotland, now more

valuable to the archicologist than the lawyer.

BURGH OF BARONY, or BURGH OF REGALITY, is a corporation analogous to a royal burgh, consisting of the inhabitants of a determinate tract of ground within the barony, erected by the king and subject to the government of magistrates. The right of electing magistrates is vested by the charter of erection, sometimes in the baron or logd of the regality, and sometimes in the inhabitants themselves.

Buggu Royaz, a corporate body erected by charter

from the crown, conferring upon it certain powers and privileges. The corporation consists of the magistrates and burgesses of the farritory erected into a burgh. The magistrates are generally a provest and bulks, desi of guild, tressurer, and common conneil. There are 68 royal burghs in Scotland; and under the Reform Act, 23 of the 53 M.P.'s for Scotland are returned by the royal burghs. The election of magistrates is now regulated by 2 & 3 Will. IV. c. 76, and in burghs not royal burghs. royal, but contributing to return members to parliament, by 3.2.4 Will. IV. c. 77, and 4 & 5 Will. IV. e. 86. The act 16 & 17 Vict. c. 28, provides for the supplying of racancies in town councils of burghs conint on null and irregular elections. The police of Sequent on and and irregular electrons. The poince of burghs and other populous places, and the paving, drawing, cleaning, lighting, and improving the same, are regulated by 13 & 14 Vict. c. 33; and the 16 & 17 Vict. c. 38, enables burghs to maintain and improve their harbours. The exclusive privilege of trading in burghs is abolished by 9 & 10 Vict. c. 93. The transferior of recovery within burghs is resulted. mission of property within burghs is regulated by 30 & 11 Vict. c. 49. A convention, composed of commissions from each of the royal burghs, meets unmally at Edinburgh, with power to make regulations for promoting the trade and commonweal of the tracels. burghs.

Turgus.

BUBGLAEY, ber'-gld-re(Lat.burgi latrocinium), in Law,
mocturnal housebreaking, which, by our ancient law, was
called hamesecken, as it is in Scotland to this day. The definition of a burglar, as given by Sir Edward Coke is, "he that by night breaketh and entereth into a mausion-house with intent to commit a felony." The breaking and entering a dwelling-house by day, to steal property therein, amounts, however, to a felony. As regards the offence of burglary, by the 7 Wm. IV. & 1 Viet. 886, t.e. 4, the night is considered as commencing at nine in the evening, and concluding at six in the morning. It is generally applied to breaking into a mansion or dwelling-house; for no distant barn, warehouse, or the like, is under the same privileges; nor is a house in which no one resides, unless the inhabitant has only left it for a short season, animo revertendi. If the building broken into communicates with the dwelling-house. either immediate or by means of a covered and inclosed passage leading from the one to the other, the breaking into it is burglary. The offence extends to breaking into a room or lodging in any private house, the mantion for the time being of the lodger, if the owner doth not himself dwell in the house, or if he and his lodger enter by different outward doors; but if the owner himself lies in the house, and has but one outward door at which he and his lodgers enter, such longers seem only to be inmates, and all their apartments to be parcel of the one dwelling-house of the owner. There must be both a breaking and entry to complete the offence, but they need not be done at once. The breaking extends to taking out the glass of, or otherwise opening a window, picking a lock or opening it with a key, lifting up the latch of a door, or unloosening any other fastening which the owner has provided; or the introduction of any part of the body, or the insertion of an instrument, or stepping over the threshold, or putting in a hook to draw out goods, or a pistol to demand one'r money. If a person leave his door or window open, the entering is not a burglary; but if an inner or chamber door be also constitute the offence ; viz .- to come down a chimney, to knock at a door, and, on its being opened, to rush in with a felonious intent, or, under pretence of taking lodgings, or otherwise, to fall upon an inmate and rob him; a servant to open his master's chamber door with a felonious design, or any other person design in the same house, or in a public inn, to open him deather another's door with such evil intent; or a servent to conspire with a robber and let him into the house by night. There must be a felonious intent, while wise the entry, actual or constructive, will amount only to a trespare. The intent is a question for the jury Whosoever shall burglariously break and enter into any dwelling-house, and shall assault with intent to murder

than three years; and in case of imprisonment, hard labour and solitary confluenced may be apperaided. BURGOMASTER, OF BURGERMETERM, best-go-secr-ter, is the title of the chief magistrate in a municipal term in Holland and Germany, corresponding to the English mayor and the French maire.

BURGORET, 'bur'-go-net, a helmet which formed part of the armour worn at the close of the 17th century.

It was invented by the Burgundians, and from them received its name. All the armour of that period was richly decorated and fluted. The burgonet took the form of the head more closely than the helmets in previous use, and frequently had overlapping plates of steel that protected the neck. There There s a resemblance between the burgonet in the accompanying illustration and the singular helmet worn in the reign of Richard II. A serrated ridge usually ran from the summit, and a plume of feathers either stood up from the apex of the helmet, or one long flow-ing plume was inserted in

DURGONET.

the pipe at the back. This plume streamed behind the wearer, frequently descending lower than the waist.

BURGON LUSTRE, boor'-gos lus-ter, a certain method of gilding ceramic ware by the double sulphide of gold and potassium, prepared by heating gold in a fine state of division with sulphur and carbonate of potash.

BURGUNDIANS, BURGUNDI, or BURGUNDIONES, bur-

gun'-di-ons, an ancient Germanic race, originally in-habiting the country between the Oder and Vistola, about the present New Mark and the southern part of West Prussia. They were distinguished from the other Germansby living together in villages - burgens (whence perhaps, their name). Afterwards they were driven out of their territory by the Gepide, when they passed westward and settled in the region of the Upper Rhine. In the beginning of the 5th century they seitled, with other German nations, in Gaul, and established themselves between the Aar and the Rhone. They are said to have been converted to Christianity in seven days. From 407 to 534, the kingdom of Burgundy was barassed by internal as well as external dissensions, being sometimes under one king, sometimes under several. In 451, one of their kings, Gundicar, engaged Attila, but was defeated and slam. In 534, King Godemar was slain in battle, and Burgundy became a Frankish province. In consequence of the weakness of the later Carlovingian kings, the country, in the latter part of the 9th century, became once more independent; and from being the residential city of Boso, the first king, it took the name of the kingdom of Arles. After various changes, Burgundy became finally united to France, on the death of Charles the Bold without male issue, in 1477.

BUBGUNDY PITCH, bur'-gundy, a resinous substance used for making plasters. It is prepared from common frankincense, the resin of the spruce fir (Abies excelse), by melting it in hot water immediately after it has been scraped from the tree, and then straining it through a cloth. The resin is thus freed straining it through a cloth. The resin is thus freed from mechanical impurities, while it loses some of its volatile oil. The substance sold as Burgundy pitch is often a factitious compound, consisting of resur ren-dered opaque by the incorporation of water, and coloured by palm oil, or else a cheap preparation of concrete American turpentine.

BURIAL, ber'-ri-al (Ang. Saz. birgan, to conceal), the act of interring the body of a deceased person. Of the various modes of disposing of the dead, that of inhitdwelling-house, and shall assault with intent to murder mation appears to have been the most amoient, as it is any person being therein, or shall stab, cut, wound, best, or strike any such person, shall be guilty of felowy, and shall suffer death. For common burglary, the punishment is transportation for life, or not less than commonly practised among the Greeks and Romans, and appears to have derived its origin from the

dread of inhuman treatment to them after death; but the practice appears to have gone out of use during the Empire. Almost every nation has manifested a certain degree of solicitude and care in the disposal of their dead; and both in sacred and profane history we find that burial was regarded as a matter of the highest importance. Among the Jews the deprivation of burial was looked upon as one of the most disgraceful things that could befall a man; and the ancient Greeks and Remans believed that their souls would not be admitted into the Elviain fields till their ancient Greeks and Romans betieved that their souls would not be admitted into the Elysian fields till their bodies were committed to the earth. Among the meients burials seem to have generally taken place without the cities, and this practice was followed by the early Christians. At first they had no separate burying-places, but in the time of Gregory the Greet, who was bithop of Rome anno 590, inclosures arourd churches began to be employed for that purpose, at first exclusively for ecolesisatical dimitaries pose, at first exclusively for ecclesisatical dignitaries, but afterwards for any who died in communion with the Church. There is no instance on record of a formal consecration of a burial-ground before the 6th century; and burial within charches does not appear to have taken place previous to the 7th. Monuments with inscriptions in memory of the dead were early adopted. Rxcept in times of persecution, the Christians conducted their funeral ceremonies during the day; but in imitation of the heathens, they adopted the custom of carrying torches at their funeral processions. The body was conducted to the grave smid the singing of hymns, and the practice of singing on such occasions was thus defended by Chrysostom: "What mean our hymns? Do we not glorify God and give him thanks, that he hath crowned him that is departed, that he hath delihath crowned him that is departed, that he hath denivered him from trouble, and hath set him free from all fear?" "If thou believest the things which thou sayest to be true, why dost thou weep and lament, and make a mere mock and pageantry of thy singing?" It was usual to carry in the procession palm and olive branches, as symbols of victory and joy, and to burn incense. Laurel and ivy leaves were sometimes put into the coffin; but express was rejected, as being emblematical of sorrow and mourning. It was also customary to strew flowers on the grave. It was not unusual to celebrate the Lord's Supper at the grave; and they also fell into the error of commending the soul of the deceased to God in prayer. During the procession, the taba, or trumpet, was employed, or, in some cases, rattles of wood or iron. In the 8th century the toiling of bells was introduced. The distribution of alms at funerals was not uncommon. From an early period it was customary to deliver funeral orations in praise of the decessed. The primitive Church denied the more solemn rites of burial only to unbaptized persons, self-murderers, and the excommunicated, who con-tinued obstinate and impenitent, in manifest contempt of the church censures. In the same way the burial service of the Church of England is to be read over all but such as die unbaptized, or have committed suicide, or have been excommunicated. Funeral services, as remarked by St. Augustine, are designed rather for the comfort and benefit of the living than for the dead; and hence, when denied to any, it is chiefly with the view of testifying the Church's abborrence of certain offences and of inducing others to avoid falling into them. "This office is also denied to infants not yet admitted into the Church by baptism; not so much to punish the infants, who have done no crime, as the punish the initians, who have done no crime, as we parents, by whose neglect this too often happens."—(Hock's Church Dictionary.) The burial service of the Church of England is singularly appropriate and impressive. The rubric directs that the priests and clerks, meeting the corpse at the entrance of the churchyard, and going before it, either into the church or towards the grave, shall say or sing as is there suppointed. In Scotland there is no religious service

appointed. In Scotland there is no religious service at the grave, but usually a short service is held in the house of the deceased before the body is removed.

BURIAL ACTS.—In consequence of the overcrowded state of graveyards in the metropolis, an act was passed, called the Motropolitan Interments Act, 1850. This was repealed by the 15 & 16 Vict. c. 85, 1852. The object of the legislature was to effect a disconsinuate of interments and to empower

enforce regulations of a southery character. Several other acts relating to the subject have been agree passed, whereby the objects proposed to be carried out in the city of London were extended to the provinces. These sots are the 16 & 17 Vict. c. 134, the 17 & 12 Vict. c. 87, and the 18 & 19 Vict. cc. 79 & 128, and the whole are amended by the 20 & 21 Vict. c. 81, 12 Vict. c. 1, and the 23 & 24 Vict. c. 64. These are carried into effect by burial boards, which appointed in the manner prescribed by the leading statutes, and they are subject to the control of the secretary of state for the Home department and orders. of council.

BURIAL SOCIETIES. (See FRIENDLY SOCIETIES.) RUBIALS, REGISTRATION OF. (See REGISTRATION.) BURIN, but-rin (Fr. burin, a graving-tool), the na given to the instruments or gravers with which the engraver cuts lines on a steel, copper, or zinc plate in engraver cuts lines on a steel, copper, or zinc place in making an engraving. The size and shape of gravers vary according to the breadth and depth of the lines they are intended to produce. They are made of well-tempered steel, and are generally shaped like a four-sided prism, with the lower end ground obliquely to apoint; but for very fine lines a lozenge-shaped graver is used. The steel end is attached to a handle, and thus forms a food shout flar or six inches in length. In our terms a collabor flar or six inches in length. forms a tool about five or six inches in length. In cut-ting a line, the graver is pushed gently, but fixely, in the required direction, being held in such a position that it forms a small angle with the surface of the metal.

BURITI PALM. (See MAURITIA.)

BURKINO, burk-ing, murdering a person with the intention of selling the body for dissection. Before the year 1832 there were not sufficient legal means by which bodies could be procured for anatomical pur-poses. Previous to that time the prices for subjects became very high, and tempted men to commit some horrible crimes. Among these were two nen named Burke and Hare, who, as associates, are believed to have murdored no less than sixteen persons solely for the purpose of handing their bodies over to the surgeons. Burke was tried in 1823, at Edinburgh, Hare being received as king's evidence against him. Their practice was to decoy poor people, usually strangers, into their houses, and there smother them after making them drunk. Burke was convicted and hanged, and his name has ever since been given to the inhuman crime of which he was guilty. In 1832 au not was passed (2 & 3 Will. IV. c. 75), by which the supply of bodies for dissecting purposes was put under legal superintendence, and inspectors were appointed legal superintendence, and inspectors were appended to the various schools of anatomy. This act has proved sufficient to meet the evil for which it was intended. To burke a project or a speech comes from this word, and means bringing to a sudden end.

BURLESQUE, bur-lesk' (Ital. burlers, to jest, mock), denotes a style of composition in which the humour consists in a ludicrous mixture of things high and

low, of high thoughts clothed in low expressions, or vice versa, of ordinary or base topics invested in artificial dignity. The burlesque style may exist in conversation as well as written composition, and in acting and drawing. It is, however, most common in poetry. Burlesque appears to have been unknown among the ancients; but specimens of it are found in most modern languages, particularly the Italian. Butler's "Hudibras" is a well-known example in English of literary burlesque, and "Bombastes Furioso" of dramatic burlesque. In the composition of the burdramatic burlesque. In the composition of the burlesque-acting pieces which at the present time enjoy so large a share of popularity, a great decadence is exhibited when they are compared with the classical extravaganzas of Planché, and the smart burlesques of A Beckett, Albert Smith, and Robert Brough, which deserved popularity for their literary merits alone. The apparent aim of the modern burlesque writer is to succeed by means of female attractions and "breakdowns."

BURMANNIACER, bur-man'-mi-ai'-se-e, in Bot., the Burmannia fam., a nat. ord. of monocetyledonous plants in the sub-class Pataloideæ. This order is said. This was repealed by the 15 & 16 Vict. c. 85, 1852.

The object of the legislature was to effect a discontinuance of internural internents, and to empower are herbaceous plants, without true leaves, or with restrict to establish burial-grounds for parishes, and perianth tubular, regular, superior, usually with aix divisions; stamens inserted into the tube of the calyx, 3 or 6, distinct; ovary inferior, I celled with three pariets; placentus, or 3-celled with axile placentas; seeds numerous, very minute; embryo solid.
species have no important properties.

Bunnert Frizzs, Tru, bur-set, were founded by Mr. Burnett, a merchant in Aberdeen, who, dying in 1765, left a part of his fortune to found these prizes. The interest was to accumulate for forty years at a time, and was then to be divided and given, as two springs (of not less than £1,200 and £100), to the authors of the best two essays on "The evidence that there is a Being, all-powerful, wise, and good, by whom everything exists; and particularly to obviate difficulties regarding the wisdom and goodness of the Deity; and this, in the first place, from considerations independent of written revelation; and, in the second place, from the revelation of the Lord Jesus; and from the whole to point out the inferences most necessary and useful to mankind." On the first competition, in 1815, the first prize, of £1,200, was awarded to Dr. W. Laurence Brown, principal of Marischal College, and the second, of £400, to the Rev. J. Bird Sumner, afterwards second, of £300, to the Rev. J. Bird Summer, afterwards archbishop of Canterbury. On the second competition, in 1855, 208 essays were given in, the judges being the Rev. Baden Powell, Henry Rogers, and Isaac Taylor. The first prize, of £1,800, was adjudged to the Rev. Robert Anchor Thompson, master of the hospital of St. Mary the Virgin at Newenstle-upon-Tyne, and the second, of £600, to Dr. John Tulloch, principal of St. Mary's College, St. Andrew's.

Bunning, turn'ing (Sax. byrnan, to burn), the action of fire or heat upon any combustible matter, by means of which the constituent natticles of the sub-

means of which the constituent particles of the sub-stance acted upon are rapidly oxidized and converted

into vapour and ashes, or into calx.

BURENG-GLASS, a glass lens employed to refract the heat-rays of the sun into a focus. Dr. Young, in his lectures on Natural Philosophy, describes some remarkable experiments performed with Parker's burning also which the ing-glass, which was presented to the emperor of China when Lord Macartney visited Pekin. This instrument was a double convex lens, three feet in diameter, three rais a double cover less, three leef in diameter, three inches thick in the centre, and weighing 212 pounds. Its focal distance was 6 feet 8 inches; but this was generally shortened by a smaller lens. The most refractory substance fused was a cornelian, which required 75 seconds for its fusion; a crystal pebble was fused in 6 seconds, and a piece of white gate in 30 seconds. The solar rays may also be brought to a focus by reflection from a concave mirror, or from a combination of mirrors. With a machine composed combination of mirrors. With a machine composed of 109 small plane metallic mirrors, so arranged that they all reflected radiant heat to the same spot, Buffon found that he was able to set wood on fire at the dis-tance of 209 feet, to melt lead at 100 feet and silver at rance of 2025 reet, to melt lead at 100 feet and silver at 50 feet. A glass globe filled with water will collect the rays of the sun into a focus: hence there is some danger in leaving a fish-globe or a decanter of water near a window, exposed to direct sunlight, during hot weather. (See LENS, MILEGOR, REFERCTION, REFLEC-TION.)

BURNISHER DEAD. (See BURIAL.)
BURNISHER, ber'nisher (Fr. Sp. brunir, to burnish), a tool made of agate, steel, or some other very hard highly-polished material, and used by silversmiths, bookbinders, and others, to give smoothness and lustre to rough surfaces.

Busss and Scalds, burns, skawlds, in Surg., are in-turies done to the body through excessive heat; burns being produced by fire or heated solids, scalds by heated fluids. Scalds seldom penetrate deeper than the cutis; burns, on the contrary, may penetrate to any depth. Burns are more fatal in the young and old than in those of middle life, and are more dangerous on the head or trunk than on the extremities. A burn affecting an extensive surface is more to be dreaded anecting an extensive surface is more to be dreaded than one which penetrates deeper without extending over much surface. Where the skin is blistered, cold evaporating lotions should be applied; as, camphorated spirits of wine, sugar-of-lead lotion, or cold water, so as to prevent the blisters from bursting, and to lessen the agrammation. The blisters may be pricked with a tine needle, in order to allow the serum to escape; but

care is to be taken not to admit the sir, and on to secount is the raised cuticle to be removed. When the account is the raised cuticle to be removed. When the cuticle is destroyed, and the inflamed outle exposed, spirit of turpentine is the best application that can be used in the first instance. A mixture of line-water and milk, or of line-water and olive-oil, will also be found useful? In more serious cases of burning, arising from clothes taking fire, the explosion of guspowder, &o., the patient frequently, immediately after the accident, falls into a state of collapse, occasioned by the shock. He suffers no pain, and the pulse is quick, weak, and scarcely to be felt. Stimulants, as brandy, are to be freely administered, to prevent the patient from dying from the shock; and warm lime-water and oil or milk, or spirits of turpentine, are to be applied oil or milk, or spirits of turpentine, are to be applied to the parts: the collapse may last for several to the parts: the collapse may last for several hours, and, if not fatal, is succeeded by a stage of reaction: the patient becomes sensible, the pulse rises, pain begins to be felt, and, perhaps, vomiting takes piace. When the reaction has been established the stimulants should be laid saide; and now inflammation has to be guarded against. This stage is characterized by the usual local and constitutional symptoms attendant on inflammation. In the antiphlogistic treatment now adopted, much care has to be observed, as it is necessary to keep up the patient's strength. Poultices may be applied to the deeply-burnt parts, in order to expedite suppuration and the separation of the sloughs. When the sloughs have separation of the sloughs, when the sloughs have separated, and suppuration is established, icatrization commences. The poultices are now to be laid aside, and moderately stimulating continents to be applied. Great care is to be taken at this stage to preserve the parts in a proper position, as in cicatrization there is a great tendency to contraction, and naturally distant parts may be brought together, and much inconvenience or deformity may be the result. Extensive burns may prove fatal in any stage, and the patient, especially if young, or advanced in years, can seldom be pronounced free from danger until cicatrization has been completed. In the event of one's clothes taking fire, it is obvious that the upright posture is not only favourable to the spread of the flames, but allows them to reach the more important parts of the body, as the head and neck; while running about only tends to in-crease the power of the flames. The best thing, there-fore, to do, is to lie down and roll about on the floor, and, if possible, to seize the hearth-rug or table-cover, and envelop the body in it. The first thing for a person to do in being called to assist on such an occasion, is to snatch up a rug, blanket, or other woollen article, and envelop the body of the sufferer closely in it, which will have the effect of extinguishing the flames. In removing the clothes from the burnt parts great care is to be taken not to break any blisters that may be raised, as a great object is to exclude the air from raw or inflamed surfaces. A course frequently adopted in such cases is to cover the parts with flour, or to wrap them in wadding or cotton wool, so as to exclude the air; but the treatment indicated above is generally preferable.

BURNT-OFFERING. (See SACRIFICE.)

BURNT SIRNNA, burnt si-en'-nd, a transparent orange red pigment, used by oil and water-colour painters. It is made from burnt terra di Sienna, an ochreous ironearth. It mixes well with other pigments, and very fine greens are obtained by mixing it with Prussian blue. One of its chief advantages is that it dries quickly.

BURNT UMBER, um'-ber, a semi-transparent russet-brown pigment. It is made from umber, an nebreous earth containing manganese, found near Umbris, in Italy. It mixes well with other pigments and dries Italy.

quickly.

BURSE MUCOSE, bir'-se mu-co'-se (Lat., muons-bags), in Anat., are small membranous sacs, situated about the joints of the bones, and containing a kind of mucous fat, which serves to lubricate the joints, in order to render their motion easy. They are of different sizes and firmness. *Bursalogy* is the name given to a descrip-

tion of the burse mucosa.

BURSARII, bur-sai'-ri-i (Lat. bursa, a purse), the receivers or accountants at the bursaria, or exchequer,

of collegiate or other conventual bodies.

Bussawy, ber'-sa-re (F., bourse; Lat. barsa, a purse.)

## Bursch

is a sum of money allowed to a student at a university to enable him to prosecute his studies. The money is usually the annual proceeds of a bequest left by some private individual for that purpose. To is said that the private individual for that purpose. It is said that the institution of bursaries originated with the Poles in institution or oursaires originated with the Foles in the 14th century, who were acoustomed to supply promising young men with the means of travelling to Germany, and there studying philosophy under the monks. This practice was soon adopted in other countries; and now there is, perhaps, no civilized country in which such endowments do not exist, under the name of bursaries, exhibitions, fellowships, scho-larships, &c. They are of two kinds,—either for fur-nishing the student with the means of prosecuting his studies during the academical curriculum, or to devote himself to literary pursuits after that period. It is to the former of these that the term bursary is applied. In the Scottish and continental universities the former is the mode in use, though recently, in Scotland at least, the latter method has been introduced; at Oxford and Cambridge both methods prevail. (See EXHIBITIONS, SCHOLARMHITS, FELLOWSHIPS.) As already stated, bursaries, at least in Scotland, have in almost every case been founded by the munificence of private individuals. and generally with a view to securing the benefits of a liberal education to those who would not otherwise have the means of obtaining it. Some were to be adjudged by public competition, others were to remain in the presentation of the heirs of the donor; some were restricted to persons of certain names, others to persons born in certain parts of the country. The bursaries connected with the Aberdeen university are more numerous than those of any other of the Scottish universities. The number of bursaries connected with the two colleges Marischal and King's was 253, of the annual value of £3,150; but, by ordinances of the University Commissioners in 1862, the number has been reduced to 189, and their annual value to £2,770. The number of prizes or scholarships, which were formerly of the annual value of £235, has been raised to 16, of the value of £925. The tendency of late years has been more and more to alienate the bursary funds from their original destination and to bestow them as prizes for superior scholarship, or as inducements to persons after completing their scademical curriculum, to devote themselves to literary pursuits. This, we think, is to be regretted; for, while there may be some truth in the assertion that, where numerous, as in Aberdeen, they tend to induce persons to enter the learned professions who are not naturally fitted for them, yet when disposed of solely for scholarship on entering the university, as the great majority of them are, -and when the examination is mainly or solely confined to one branch, as Latin version-writing, then, we believe, that in many cases persons of talent and ability who have an many cases persons of talent and annuly who have struggled through great hardships to attain a certain amount of education, are denied the means of pro-ceeding farther, and that it was such cases that the founders intended to meet. Such persons, who may have had to thank a country parish school for all the instruction they have received, cannot compete on equal terms with those who have enjoyed the advantages of a long and thorough training under the best masters. The bussaries, too, being bestowed for scho-larship, have come to be viewed in the light of prizes, larship, have come to be traved in the light of prices, and we believe, in the majority of cases, are held by persons whose parents are well able to pay for their education. While so much is done for scholarship, we confess we should like to see something done for young men of promise, desirous of obtaining a liberal educamen or promise, desirous of dotaming a liberal educa-tion, without the means of doing so, and who, we cannot help thinking, have the first claim to be considered in the disposal of the bursary funds.

BURSCH, or BURSCHE, boorsh (Ger.), is the desig-nation applied to a student at a university in Ger-

BURSCHENSCHAFT, boor shen-shoft, was the name of an association of the students in Germany, formed in 1815, and which had for its object the political regeneration of Germany.

Bursers, bir-eard (so named in honour of Burser, the naturalist), in Bot., a gen. of plants belonging to the nat. ord. Amyridaces. The species B. gummiferu pomene in the Vil and acuminata yield fragrant resinous substances, that buskin, and it form the former being termed Chibou, or Cachibou costume of Diana.

#### Buskin

esin, and that from the latter, resin of Cares genus, with some other genera of Ameridaces, cluded by many botanists in a nat. ord. termed I

BURYING-BERTLE (Necrophorus), a gen. of Cal-tera, found in Europe and North America. The ptere, jound in nurope and Norm America. They have received their name from a remarkable habit they have of burying the bodies of dead birds more, moles, and other small animals, in which they deposit their eggs. One of the species is a native of Britain, the Necrophorus Vespillo. It is a black-beetle about an inch in Land. inch in length, and has two bright orange bands acro the back. It has an intensely fortid door, and the hands smell for hours after touching it. In some parts of Russia, where poor people are buried only a lew inches beneath the surface of the ground, the burying-beeties pierce the graves in every direction. In this country they feed upon putrefying dead bodies and the garbage that is thrown out near towns, as soon as it begins to smell. They hunt in couples, and as soon as they find a dead bird or mouse, they alight upon

BURYING-BEETLE.

it, and, after feeding, the male commences his work of interment. This is done by digging with his head alone a trench round the dead object; a second trench is then dug within the first, and then another, until the earth is cultiely excavated. The dead bird or mouse then fails into the hole thus formed. Much time and labour are expended in this work. As soon as the corps is fairly dragged to the bottom of its grave, the beetle quickly throws back the removed earth, and both insects bury themselves in the body. After the female has deposited her eggs, the pair work their way female has deposited her eggs, the pair work their way out. The eggs are quickly hatched. The larvæ are whitish, with six feet and a brownish head. When perfect insects, they make holes in the ground, and

work their passage to the outer air.

Buskin, bus-kin (Ang.-Sax.), the English translation of the Latin word cothurnus, which was a kind of boot, covering the foot, and rising above the calf of the leg.

sometimes even reaching as high as the knee. It was principally worn by hunters, horsemen, and persons of rank and authority. The sole of the bus-kin was generally of an ordinary thickness, but ordinary thickness, sometimes it was made thicker than usual by the insertion of slices of cork. The object here was to add to the stature of the wearer; for which reason it was worn by the Greek and Roman tragedians, in order to give them a more heroic

BUSKIN.

carance, as the soccus, or low-heeled shoe, was worn by the comedians. Hence, in English, the buskin and suck have come to be synonymous with tragedy and comedy; as in Dryden,-

Great Fletcher never treads in buskins here, Nor greater Jonson dare in socks appear.

It was also worn by ladies for ornament. The Melponene in the Villa Borglesse is represented with the buskin, and it forms part of the recognized hanting

## Bush

Bran, seek (Dan bosch), in Bot., a low diminutive shrub, with numerous branches near the base.

Bushki, bush'el (Fr boissesse), an English measure of capacity for dry goods, as fruits, grain, &c., and constaining fear peaks, or eight gallons, or one-eighth of a quarter. Until the year 1826, from the reign of Henry VIII., a Winchester bushel was the legal measure of England; but by the 6 Geo. IV. c. 74, it was superseded by the imperial bushel. The imperial bushel is the standard measure of capacity for coals, lime, fish, metatose, or fruit as well as all other goods. lime, the potatoes, or fruit, as well as all other goods commonly sold by heaped measure. It should contain 90 lbs. workdupois of distilled water, should be made round, with a plain and even bottom, and be 194 inches from outside to outside. Du Cange derives the name from basselus, a corrupt Latin word for a measure of wine equal to eight gallons.

Buss, Palm. (See Manicaria.) Buss, bust (Ital. busto), a term in Soulp., by which is Box, sust (1tal. busto), a term in Soulp., by which is meant a representation of the head, neck, shoulders, and breast, with, most frequently, the arms cut off midway above the elbow. The derivation of the word is uncertain, as the lat. bustom first meant the place where dead bodies were burnt, then the grave, and lastly, in later ages, was taken to signify the dead body, or rather a body without the

head. The representation of the upper part of the human form, as shown in the bust of sculpture, is supposed to have originated with a custom in vogue among the ancient Greeks of placing heads of Mercury on pillars, whence they were called Herme, from Hermes, the Greek name of that divinity. Busts were first used as portraits of men of renown, as warriors, statesmen, poets, philosophers, &c., about 330 B.C. The method of taking a cast in plaster of Paris from the human body is said to have been first

practised by Andrea Veroc-chi, an Italian, about the middle of the 15th century. By the sid of the plaster cast the sculptor is enabled to produce a very accurate portrait of the original, and in this branch of art English sculptors have attained a high degree of excellence. Among sculptors that are famous for their portrait busts, Sir Francis Chantrey stands pre-eminent.

Chantrey stands pre-eminent.

BUSTARD, bus-tard (Fr. bistards).—This is the largest of European land birds. When full grown, the Great Bustard (Oits tards) weighs from twenty-five to thirty pounds. It is about four feet long, and across its extended wings measures three yards. The head and notes are ash-coloured, and there is a tuft of feathers about five inches long on each side of the lower mandible. The bustards generally live in open countries dotted with low bushes, a locality which gives them the advantage of a broad look-out and secures them from surprises by enemies. They are said seldom to use their wings for acrial locomotion, but as adjuncts to their long legs in running. The speed they make this way is considerable, and may be sustained a very long time. The bird is still found in parts of France and Germany, and is common in Russia and on the extensive plains of Tartary. In this country, however, it has long been rare. Yet that they were sometimes common as cortain, so common as to be a looked-for dish at feasts and banquets. A living and reliable naturalist speaks of the circumstance being in his remembrance, of seeing one, and sometimes two, bustards gracing the Christmas board of the Bush inn at Bristol. In 1799 a bustard was taken alive on Salis-In 1799 a bustard was taken alive on Salisbury Plain, and, according to Stanley, the latest au-thentic instance of a capture of this bird is that of a gamekeeper in Norfolk, who took a hen bustard in a rabbit-trap, in May, 1829. One of the bustard's chief peculiarities is a singular pouch, shaped like a modern base of the lower mandible. The real use of this pouch sare of the lower mandible. The real use of this pouch parts of its plumings; pair base of the lower mandible. Douglass supposes that the bird fills it with water in the midst of the arid plains over country is only a rare winter visitant. When contrad

## Butcher-bird

which it is accustomed to wander; but as the possib peculiar to the males, this would seem, at least, in probable. Bewick has his opinion on the subject, as Stanley has his; but what can be said when Mr. Ya one of our best and most paintsking naturalists, hints broadly that it is altogether a blunder—that he has dissected a male bustard, and dissevered no posset all. With regard to the food of the bustard, as great diversity of opinion exists. Pennent declares

food to consist of corn and other vegetables that grow in their neighbourhood; Brookes asserts that their proper food is frogs, mice, small birds, and various kinds of insects; and Montagu, that vegetables (especially turnip-tops) and earth-worms form the staple of the bustard's aliment. The Little Bustard (Otis Tetrao), though common in France, Sardinia, and Italy, is very rarely seen here: it is also found in North Africa, Turkey, and Greece. It is about eighteen inches in length. It is a very shy bird, and when disturbed, escapes by alternately running and flying.

BUTCHER, but'-cher (Fr. boucher), a slaughterer of cattle for the table; also a vendor or retailer of the same. The methods of killing cattle vary in different countries, as do the means by which the mean is disposed of to the cousumer. In London, the carcass-butchers kill the saimals, and sell the meat in large quantities to the retail butchers, who afterwards sell it to their customers. Napoleon I., in 1809, judiciously removed the slaughter houses, which were receptacles of fifth and injurious to health, to the outskirts of Paris. In all countries the Jews have their own butchers, who are licensed by the rabbis, and who, instead of knocking down the unimals, according to the usual practice, cut their throats. The method of killing cattle by cut their throats. penetrating the spinal marrow is practised in some countries; and it has even been suggested, by some bumane persons, that the animals should be subjected to the influence of chloroform, that they might die without pain or struggle.

BUTCHER-BIRD (Lanius excurbitor).—The sunguin-ary title of this member of the Shrike family, received from Gener two hundred and fifty years ago, arises not only from its savage and cruel disposition, which seems to lead it to kull for the pleasure of killing, but also from its singular habit of impaling its victime on thorns and twigs, and in that position tearing and devouring their carcasses piecemeal. birds have the strongest autipathy to the batcher-bird, and will express their rage and fear by the londest cries should one appear in their neighbourhood. It is about the size of the common thrush. Its bill is black, and furnished with bristles at the base; the upper parts of its plumage, pule blue, and its under-parts white. It is common all the year in Erance, but in this

382

#### Butcher's Broom

in a cage, the same love of fixing its food before it tears it to pieces is discovered, and for this purpose the bird usually avails itself of the wires of its prison, to which it hangs its dead captive. A bird of this species remained in the possession of a friend of Mr. Yarall for trajler months; it hearns are the contractions of the contraction of th sell for twelve months; it became very tame, and

BUTCHER-BIRD.

would readily take food from its master's hands. When a bird was given to it invariably broke the skull and ate the brains first. It sometimes held its prey in its claws and pulled it to pieces in the manner of the hawks, but seemed prefer forcing part of it through the wires of its cage and pulling at it. It always hung what it could not eat to the sides of its cage. It would often eat three small birds in a day. Another of these shrikes (Lanius collaris), a nativo of

exhibits this carcass-suspending propensity in as marked a manner as the above. The Hottentots assured Le Vaillant that this bird does not prefer fresh food, and that its motive for hanging its carcasses was much the same as prompts some of us to hang venison and game. A curious result sometimes follows this habit of the African shrike. Beneath the scorehing sun of that region the process of decom-position does not always take place, from the rapid exhalation of the animal moisture; consequently, the trees and shrubs are sometimes found bearing amongst their fragrant buds and blossoms many ready-dried specimens of the small birds of the country. .

BUTCHER'S BROOM. (See RUSCUS.)

Burna, bu-te'-a (named after John, earl of Bute, great patron of botanists), in Bot., a gen. of plants belonging to the nat. ord. Legaminose, sub-ord. Papi-lionacea. The most important species is B. froncosa, s native of India. This tree yields an astringent gum called butea gum, which resembles kino in its properties, and is sometimes forwarded to this country under that name. It is used medicinally in India in rhoma and similar diseases; also for tunning. It is used medicinally in India in diardried flowers of this species and those of B. superba are known as Tisso and Kessaree flowers, and are extensively used by the Indians in the production of beautiful yellow and orange dyes. The fibres of the inner bark of B. frondosa are known under the name of Pulas cordage.

BUTOMACKE, bu-to-mai'-se-e, in Bot., the Butomus or Flowering Rush fam., a nat. ord. of monocotyledonous plants in the sub-class Pelaloidea,—aquatic plants with parallel-veined leaves, sometimes milky. Flowers perfect and showy, with inferior perianth of six pieces arranged in two whorls, the inner being coloured; oraries superior, 3-6, or more; ovules numerous, arranged all over the inner surface of the ovaries; fruit many-seeded, separating more or less into as many paris as there are component carpels; seeds without albumen. The Butomocess chiefly inhabit the northern parts of the world, but a few occur in tropical countries. There are four genera and seven apecies.

BUTONES, bu-to'-mus (Gr. bous, an ox; temmo, I out), in Bot., the typical gen. of the nat. ord. Ituto-masses. B. unbellatus, the common flowering rush, is frequent in ditches and ponds in England and Ireland, but is very rare in Scotland. The leuves, which spring from the crown of the root, are from two to three feet long and of a triangular shape. The scape or flowering stem is longer than the leaves, and terminates in a large umbel of rose-coloured flowers. The plant possesses

## Butterfly

norid and bitter properties, and was in medicine. The rotated thisome sharp leaves of the Butones were be mouths of the cattle that cropped it— Burres, but ter (Bax, buter, buters

Burres, but ber (Bax buter, buters ? Ger. but Lat. butyram).—Buter is the fatty part of the mill milks separated by the process of chuming. On milk is composed of three ingredients,—the cha-portion or curd, the when on milk is composed of three ingredients, the che portion or eard, the whey or watery part, and butter. Milk when examined by the microscop found to consist of a number of fatty globules float in the whey. These globules, which are little a containing the butter, are broken during the proof churning, which allows the liberated fatty matter agreement in which have the state of the proof of the pr aggregate in small masses and float on the top of t wher. These are generally united by pressure against the bottom of the churn, and the remaining butters milk is given as a drink to pigs. The butter is afterwards spread out in a thin layer in a shallow pau, and washed with clear spring water to free it from buttermilk that may remain in its pores. It is then formed into rolls if intended to be sold as fresh, but if it is to be kept for any length of time, it is mixed with salt, in the proportion of three or four pounds of salt to half a hundredweight of butter, and packed in casks for the market. The quality and quantity of butter contained in cowe milk depend materially on the nature of the pasture. Rich natural meadows afford the best food for cows intended to produce butter. Poor pastures are objectionable, not only from the quantity of butter contained in the milk being diminished, but from its receiving an unpleasant tast from certain plants or weeds growing on all unfertile or marshy soil. The amount of butter produced by a gailon of milk should be from three to four ounces. Butter is much adulterated with water, dripping, and mutton fat. The first may be detected by the wetness of the butter when squeezed, and the two last by small white particles being visible in the newly-cut surface of the butter. The consumption of butter in London is or the butter. Lie consumption of butter in London as estimated at about 15,000 tons annually. About 400,000 ewt. of foreign butter are annually imported from Holland, Belgium, and France, and from 100,000 to 120,000 ewt. of Irish butter are annually sent to Possible 120,000 ewt. of Irish butter are annually sent to Possible 120,000 ewt. tugal and Brazil.

BUTTER OF ANTIMONY, terchloride of antimony. See Antimony.)

BUTTER OF SULPHUR, an obsolete name for precipitated sulphur.

BUTTER OF TAN, bickloride of tin. (See Tin, Culo-

BUTTER OF ZINC, chloride of sinc. (See ZINC,

CHLORIDE OF.)

BUTTER, VEGETABLE, a name commonly given to any concrete oil of vegetable origin which at all resembles the butter obtained from soimal milk, or which is employed for similar purposes. The most important solid oils or fats procured from plants are,—Butter of solid oils or fats procured from plants are,—Butter of cacao, from Theobroma Cacao; of cinnamon, from Cinnamonum zeylunicum; of nutmer, from Myristica moechata; of cocoa-nut, from Cocos marifera; of laurel, from Lauran nobilis; Shea or Calam butter, from species of Bassia; palm-oil, from Elais ghimnensis; and vegetable tailow, from Stitlingia schifera in China, from Vateria indica in India, and from Pentadessabutyracea in Sierra Leone. All these oils contains alarge proportion of stearine, and many are used as substitutes for animal fat in candlemaking. The plants yielding them are frequently termed butter-trees. trees.

BUTTERCUP. (See HANUNCULUS.)
BUTTERFLY, bull-ter-fly (so hamed from the colour of the yellow species; Sax. butterfleye), the name of an extensive group of the ord. Lepidoptera which fly by day. They are distinguished from other insects by these generic characters:—The antenne are terminated by a knob, or at least are somewhat suddenly thicker at my a mon, or at seast are somewhat suddenly thicker at the extremity; by the beauty as well of the under as of the upper side of their wings, which are usually erect when the animal is in a state of repose. They possess four wings, covered with minute scales, which to the naked eye appear like powder. "If you divide the wing of any butterfly, which you may easily do by soraping is on both sides with a penkfife, you will be smused to trace the lines in which the scales were planted, con-

## Buttermilk

sisting of iunumerable minute dots; the lines of the under side, in some cases, so out those of the upper side as by their intersection to form lozenges. With regard to the position of the scales on the wing, they rangally lie flat, but cometimes their extremity is in-curred."—(Airly and Spence.) The number of British Papilionida is not more than seventy, and at least two-thirds of this number are to be met within five-andtwenty miles of London; and it singularly happens, that some of these affect particular localities, sometimes of an area of but a few acres, and are never elsewhere seen. Even on such favourable spots their appearance is limited to a few days in a certain season of the year.

Another neculiar circumstance in the history of these insects is, that several species appear in certain localisation. ties, at intervals of several years, when they will literally swarm; come the next season, and not a solitary one will reward the most diligent searcher. This might be attributed to the variable character of our climate, but it is well known that in tropical countries the same irregularities occur. The external form of the chry-salids varies according to the species of butterfly that inhabits them; in all, however, there are spertures opposite to the thorax, by which respiration is carried on during the whole period of their inactive state. When the entembed creature has acquired sufficient vigour, and the down already grown upon it has separated it on all sides from the shell, the latter is broken through by the insect's head, and it emerges a butterfirst, however, the wings are closely folded to its body; but they soon expand of themselves, and are sufficiently hardened by the sir to endure the effort of flying. It, however, is not every chrysalis that be-comes a butterfly, probably not a thousandth part of their number do. Both in a caterpillar and in a perfect state they are surrounded by ever-hungering enemies. state they are surrounded by ever-hungering enemies.

Many species of the Ichneumonide perforate the hody of the caterpillar and there deposit their eggs; and although the caterpillar continues to live, and is transformed into a chrysalid, no butterfly is produced from it, those internal parts which were essential to its perfection being consumed. Sparrows and other birds are mortal foes to butterflies, and a single pair will active the force of the part will be the part of the pair will be the part of th easily dispose of between three and four hundred in the course of a single week

BUTTERMILE, but'-ter-milk, the milk which is left after the butter has been separated by means of churning, or other processes. It is ordinarily procured from milk after it has been kept some time, and has become more or less acid; but it may be procured from new milk when it is not acid, and only differs from milk by the absence of its oily parts. In this state it is still tolerably nourishing, and, being easy of digestion, is toperacy noursaing, and, being easy of digestion, is employed in phthicial cases with greater advantage than either the entire milk or the watery parts of it in a more acid state. The acid of buttermilk does not increase the acescency of the stomach, or occasion the flattlency usually generated by vegetable acids.

BUTTERWORT. (See PINGUICULA.)

BUTTERWORT. (See PINGUICULA.)
BUTTORS but'-tons (Fr. boutons), articles of dress
sed either for fastening or for ornamental purposes. Buttons are made of an endless variety of materials, the processes employed in the manufacture varying secording to the substance used. Metal, wire, wood, bone, glass, shell, mother-of-pearl, precious stones, selvet, silk, and other substances are used. Birmingham is the place where they are most extensively manufactured. They are made in a great variety of chapes; but, at the present time, these may be classed under four heads, —buttons with shanks; buttons without shanks; buttons on rings or wire moulds; and bustons covered with cloth or other material. Buttons with slignly are usually made of brass, which is supplied to the manufacturer in sheets of the required thickness. By means of fly-presses and punches, circular disks sailed blanks, are cut out of these sheets. This is mostly performed by females, who can furnish about thirty blanks per minute, or twelve gross in an hour. Hand-punching is the general mode of cutting out blanks; but more complicated machines, which out out

#### Buttress

them to receive a sharp blow from a polished steel hammer. In this state they are ready to receive the shanks, or small metal loops by which they are attached to the dress. The shank manufacture is a distinct branch of trade in Birmingham. They are made by a machine in which a coil of wire is gradually advanced towards. machine in which is only wire in greaturery are received a pair of shears which outs off short pieces. A metal finger then presses against the middle of each piece, first bending it and then pressing it into a vice, where it is compressed so as to form a loop; a hammer then strikes the two ends, spreading them into a flat surface, and the shank is pushed out of the machine ready for use. The shanks are attached to the blanks by women, with iron wire, solder, and resin. They are then put into an oven, and, when firmly united, form plain buttons. If a crest or inscription is wanted, the button is placed in a die and stamped. After being cleaned, they can be silvered or gilt. (See GILDING.)
The manufacture of gilt buttons has fallen off greatly overed with cloth. Horn buttons are that of wire sure, the horn being previously setted by heat. In 1851, there were 6.938 persons employed in the button manufacture in England; of these, 4,980 were employed in Birmingham.

BUTTERSS, but'-tress (Fr. buttee, from aboutir, to abut), a piece of masonry or brickwork projecting from the face of a wall, and giving it support and increased strength and solidity. In Grecian and Roman architecture the buttress was not used, but its place was occupied by a pilaster, or some slight projection in that form. The buttress washirro-

duced with Gothic architecture in the Mediæval period, and, by degrees, it was formed into a very ornamental addition to the building to which it was attached. Norman buttress was a flat projection, fluished with a slanting coping, jutting slightly over the face only, and not over the sides; there was generally a band round the lower part, which formed a con-tinuation of the capping of the basement, and if the basement projected beyond the face of the wall, the face and sides of the bottom of the buttress projected to a similar extent, forming a sort of rediment on which the upper portion rested; with this exception, its depth was the same throughout from top to bottom, but never very great; its face was generally broad. Some-times the Norman buttress is found in a semicircular form. Good ex-amples of this style, from its earliest adoption to the Transition period, may be found at Fountain Abbey, the ruins of the abbey at Glustonbury, and Norwich Castle. The chief characteristic of the Early English buttress is, that it projects from the face of the wall to a much greater extent than the Norman buttress, its depth being equal to, and sometimes more than, its breadth. It generally consists of two or three divisions or stages, each division being less in depth

than the one immediately below it, and finished with a water-table, or stone bevelled to present a single incined enrince, or a series of site-iaces, like shallow steps, one above another. The tops are generally finished in a triangular or pointed form, resembling the gable-end of a house, and the roof pre-jecting over it. Examples will be found at Canterbury Cathedral and the majority of Euglish parish churches. The buttresses of the Decorated English style are simi-lar, in ganges forms to these of the present a single inclined surface, or a series of surregister ten blanks at a time, are in use. After being punched, the edges of the blank are very sharp, and requires to be smoothed and rounded. Their surfaces are then planished on the face by placing them see then planished on the face by placing them see them planished on the face by placing them see them planished on the face by placing them see them planished with proceedings of the better than the butters of the becomes the butters of the better than the butters of the better than the butters of the butters of

# Butta, Rifle

phuscle. The edges of buttresses of the Early Beglish and Decorated Rogish styles are offen chamfered. When they are built at the corner of a building, they project diagonally sometimes, but generally two are built, at right angles to each other, on either side of the angle. Examples of Decorated English buttresses will be found at Exeter Cathedral, York-Minister, and Waltham Gross. The Perpendicular English buttress differs from the buttresses already mentioned in being divided into a great number of stages, with panels in front and at the sides, filled with rich tracery. They are higher, and have small pieces, in the form of a breakes or capital of a column, rising from the wall-plate at the top of each stage, which serve as pedestals for small statues. King's Collego, Cambridge, and St. George's, Windsor, furnish good examples of this kind of buttress. Flying buttresses pre buttresses built against the walls of the side-sisles of cathedrals and large churches, and connected with others immediately in their rear, projecting from the walls of the nave, with stonework in the form of a semi-arch, which is sometimes plant. And sometimes chaborately carved and perforated with trace-y of rich design, as may be seen in those at King Henry the Seventh's Chapel, Westminster Abbey, the cathedrals at Salisbury and Chichester, and those at Amiens and Rheims, in France, which present extraordinary examples of stonework carved with skill and taste. Flying buttresses were carved with skill and taste. Flying buttresses were

Burrs, Rible, buts (Fr. but, a mark), a term applied to a screen, generally made of earth-work and masonry, for protecting the markers during rifle-practice at a target. It is placed about fifteen yards in front of and to one side of the target, and in such a position that the markers can easily see the face of the target from it. When the nature of the ground will permit, a trench is dug, and the earth excavated is thrown up on the side of the firing. The interior is lined with stonework, and there are two wings, or epaulements, which protect the markers not only from the shots but from any stones that may be thrown up them. About eighty yards in rear of the marker's butt, a smaller butt, capable of holding two men, is placed, wherever it is practicable. The markers in these butts note the ricochet shots. The bank, screen, or earth-work against which the target leans is also called a butt.

Butti, bu'-tile (C, H<sub>u</sub>).—Butyl is an organic radicle, discovered by Kolbe amongst the products obtained by electrolysis from valerate of potash. It may also be prepared by the action of sodium on iodine of butyl, in a vessel so arranged that the volatilized products may return into it as fast as they are volatilized and condensed. When the reaction has terminated, the butyl may be distilled off at a temperature not exceeding 300° Fahr. When pure, it is a limpid oil, with an agreeable ethereal odour. It boils at 220° Fahr, and may be distilled without alteration. It is one of the lightest known fluids, its spec. grav. being only 0.694. It is the radicle of a great number of very interesting organic compounds. It has been called valyl by certain chemists, from being formed from valeric acid, and by others tetryl, from being fourth in the series of hydrocarbon radicles:—

Methyl, C<sub>2</sub>H<sub>2</sub>.
 Ethyl, C<sub>4</sub>H<sub>5</sub>.
 Tetryl, C<sub>4</sub>H<sub>9</sub>.

BUTTLE ETHER, or Oxide of Butyl, bu-til'-ik (C, H, O), was first described by Kolbe as a product of the voltaic decomposition of valorate of potash. It is at present but little known. Butylic alcohol, or hydrated oxide of butyl (C, H, O, HO), was discovered by Wurtz in bestroot moisses. It is a colourless highly refractive liquid, boiling at 225°, and has a slightly vinous adour, somewhat resembling that of amylic alcohol. Its spec, grav. is 0.803. It is quite similar in properties to the other alcohols of the same group.

BUTTLINE, bu'-4t-line (O, H, s), butyl less one equiva-

BUTTLINE, but-ine (U.H.), buty less one equivalent of hydrogen. This compound was discovered by Faraday amongst the products of distillation of oil, und is frequently called oil-gas. It is a colourless gas, burning with a white inminous flume. It is one of the principal products of the distillation of india-rubber, is was afterwards obtained by Kolbe from valerate of potent, and by Wurts by acting on butylic alcohol.

#### Burns

with obloride of zinc. It is similar in its properties to ethyline  $(C_*H_*)$ , or olellant gas, the corresponding product of ethyl.

Buyrant of Livin, but e-rait, the source of tractyric acid, is made in the following manner:—Buyrant chalk, and cheese, are mixed with sufficient water to form a solution of spec, grav. 1-070, and exposed to temperature of 80° or 90° for some weeks. Buyring fermentation ensues, the liquid becoming ropy, and giving rise to lactic acid, which unites with the time and forms lactate of lime. The lactate of limes in turn becomes decomposed, giving rise to butyrise of lime is abundance. The compounds and derigatives of lime is abundance. The compounds and derigatives of lime is abundance. The compounds and derigatives of lime is abundance. The same relation to butyr that actic acid does to ethyl, and is, in fact, the hydrasted oxide of butyryl, as acetic acid is of acetyl. Butyric ether, a combination of ethyl and butyric scid, is a colourless inflammable liquid, with a peculiar door and taste of pincapples. Dissolved in alcohol, it is used in confectionery under the name of pincapples oil. The peculiar odour of old rum is due to the presence of a small quantity of this ether. It must not be confounded with huttlie ether. (See Buyrus).

confounded with butylic ether. (See BUTYL.)
BUTYLIC ACID, bu-tir-ik (from Lat. butyrsa; butter), (HOG,H,C).—Butyric acid is a liquid with a
sharp, acrid taste and a smell of rancid butter, having a
spec, grav. of 0.973, and boiling at 314° Fabr. It is prepared by distilling three parts of butyrate of lime
with twelve parts of water and one of hydrochloric
acid. Butyric acid exists ready-formed in certain
fruits, and is one of the products of oridization of
fibrin, or caseine. All substances which form lactioacid may be made to yield butyric. Its salts, when
dry, are incolorous, but when wetted, a strong smell,
resembling that of rancid butter, is perceptible.

BUTYLINE, but'e-rine, an oleaginous substance, discovered by Chevreul in butter. It is prepared by exposing purified butter to a temperature of 66° for several days. Stearine separates in grains, and one oily compound is obtained, which is mixed with alcohol and frequently shaken during twenty-four hours. The alcohol is then distilled off, carbonate of magnesia added to the oily residue, which is washed and treated with alcohol, which, on being once more distilled, leaves the butyrine behind.

BUTTRONE, but'-e-rone, a substance obtained by Chevreul amongst the products of distillation of butyrate of lime. It is similar in properties to acctone and propione.

BUXINE, buk'-sine, an alkaloid obtained from boxwood. It has a bitter taste, and is insoluble in water. It is soluble in a slight degree in alcohol and ether. It forms neutral salt with the noids, and note as an alkali on reddened litmus. Boxwood bark contains nearly one per cent. of buxine.

nearly one per cent. of buxine.

Buxom, buk-sum (Ang.-Sax. bucsum, easily bended to the will of another), originally signified obedient or obsequious; and in an old form of marriage, the bride promised to be obedient and buxom to her husband. At present it is used in the sense of gay, lively, brisk, associated with plumpness.

Buxus, buk-sus (supposed to be from Gr. puknos, dense, in reference to the wood), in Bot., the Box, a gen. of plants belonging to the nat, ord. Emphorbiscos, and consisting of evergreen shrubs or small trees with opposite leaves, entire at the margins, and easily split into two plates. The flowers, which are very small, grow in little axillary clusters, the male and female flowers being distinct, but borne on the same plant. There are only two species known; namely. B. semper-seriens and B. bulcarica. The former, which is the common box, is remarkable, botanically, for being the most northern arborescert species of Euphorbiscoca. In Britain, it seldom attains a height of more than twelve or fourteen feet; but, in the south of Europe, it is often twice that height. It grows wild in this country only on the dry chalky hills of the south. Many varieties are known in gardens, the most remarkable of which is the dwarf-box, so much used for the edgings of walks. The wood of the arborescent B. semperviens is heavier than that of any other European tree, and will sink when placed in water. It is of a beautiful pale-yellow colour, and of a fine regular and compact texture. It is preferred to every othes

## Busserd

kind of wood for the manufacture of flutes, flageolets and other wind instruments; of rules and mathematical instruments; and of the handles to most small tools. instruments; and of the handles to most small tools. Root the purposes of the turner, the wood-carryer, and especially of the wood-engraver, boxwood is invaluable. Most of the wood-engraver, boxwood is invaluable. Most of the engraving; printed in the illnerated papers are executed on blocks of this wood. Spain and Portugal export large quantities of boxwood; so also do Circassia and Georgia, through the port of Odessa. In 1815, the box-trees cut down on Box hill, meas Dorking, in Surrey, produced upwards of £10,000; but the tree is of such slow growth, that it is seldom cultivated in Britain, except for ornamental purposes. The lesses of the common box are purgative, and have been employed medicinally. An empyreumatic oil obtained from boxwood has been used successfully for the resief of toothache. B. balearica, the Turkey, Minorca, relief of toothache. B. balearica, the Turkey, Minorca, or Balearic box, forms a larger tree than the other spe s, and has leaves three times as large. It is much more impatient of cold, but is occasionally seen in shrub-beries in the south of England. The wood is of a bright reliow, and much inferior to the true boxwood, for country in large quantities from Constantinople, and

sold for wood-engraving.

Buzzard, buz'-zard (Du. buzaard; Buteo vulgaris), a predacious and carrion-feeding bird, common to the whole of Europe. It is a sluggish bird, and its courage is not nearly commensurate with its size; for, while it measures nearly two feet in length, and its extended wings cover a breadth of nearly five feet, it will flee from the attack of a magpie or jackdaw. Like the file, the raven, and all birds that feed much on car-rion, the buzzard has a lofty flight when in search of food. In colour it is reddish-brown above, and white or cream-colour beneath; the tail is barred with black and ash-colour, and has a white tip. The bird's beak is comparatively small and feeble. It breeds in extensive woods, builds a ragged nest, and lays two or three save woods, builds a ragged nest, and lays two or three eggs, which are either wholly white or white blurred with yellow. If during the period of incubation the hen should be killed, the male bird will take upon himself the business of hatching and rearing the brood. The young accompany the old birds for some time after quitting the nest; a circumstance unusual with most birds of prey, who drive off their young almost as soon as they can fig. "In the softness and fulness of the runners are furthered large and habits." as soon as they can fly. "In the softness and fulness of its plumage, its feathered legs, and habits," writes Dr. Richardson, "this bird bears some resemblance to the owis. It flies slowly, sits for a long time on the hough of a tree, watching for mice, frogs, &c." Wilson likewise observes, that in Penusylvanis it is in the habit of coursing over the meadows long after the sun has set. The honey-buzzard, or pern (Pernis opicorus, Cavier), is a little longer than the common buzzard, and not so builty. The crown of the head is of a ways and not so bulky. The crown of the head is of a pure bluish ash-colour; the upper surface deep brown, barred with deep brown. It is said to derive its name from the partiality it shows for bees, wasps, and their larve as food. "One of these birds was shot in Pendriag-Hall Park, Suffolk. The person who killed it, saw it on the ground near some wasps' nests. I found, on secting it, a quantity of wasps and nymphæ from the comb, both in its craw and stomach, with a few small beetles. It would be highly interesting could we be made aware of the manner in which this bird conducts the attacks on the wayse nest. The buzzard in order to get at the comb, must, in some way, enlarge the intrance; the legs and claws of the bird I have mentioned were very dirty, even to the knee, most likely brom searching much on the ground for food, and using them in making an entrance into the wasps' nests."

Linguishes of Natural History.) The hony-buzzard massite Bussia, Sweeden, and Norway, and is found generally in the south of Europe. It is rare in this suniter, though the has been known to theed here. Sie generally in the south of Europe. It is rare in this sountry, though it has been known to breed here. Sir William Jardine quotes a case, as does W. R. Fisher. (See the Zoologiet.) White, in his "Natural History of Selborne," tells of "a pair of honey buzzards that built them a large shallow next, composed of twigs and lined with dead beechen leaves, upon a small, slender besch, near to Selborne Ringer. In the middle of the month of June, a bold boy climbed this tree, though training on so deep and dizzy a situation, and brought

# Byzantine Architecture

down an egg, the only one in the next. The egg we amalier and not so round as the egg of the commo buzzard, and was dotted at each and with small re-spots, and surrounded in the middle with a broad an blood-red gore."

BY-LAW, bi-law, is a private law made by those win are duly authorized to do so by charter, act of partie ment, prescription, or custom, for the preservation a ment, prescription, or custom, for the preservations order and good government within some particular place or jurisdiction. If made under an act of partial ment, they must be sanctioned and approved by the secretary of state, or some public board to whom the act gives authority for the purpose, and they are the as binding as enacted laws. They must not be against the public policy of the law, and must be reasonable and other public policy of the law, and must be reasonable. Joint-stock companies and other such bodies are em powered by their charters or deeds of settlement to

make by-laws, which are binding on the shareholders.

BYERHUS, bir-rus, a gen. of the ord. Colonters. This insect is about the size of the lady-bird, is of a deep brown colour, with its wing-shells marked by blace

lines. It is commonly found in gardens.

BYRSONIMA, bir-so-ni'-ma, in Bot., a gen. of plants belonging to the nat. ord. Malpighiaccas, consisting of tropical trees, all remarkable for their astringency. Thus the bark of B. crassifolia is used internally as as antidote to the bite of the rattlesnake, and for other purposes where an astringent medicine is desirable The barks of other species are much employed in Brazil for tanning. American alcornoque bark, which is now largely imported into this country for the use of the tanner, is said to be the produce of B. laurifelia rhopalafolia, and coccolobafolia. Several species have racquarguin, and coccoionaristic. Several species navi-edible fruits. The fruit of B. spicate is used medici-nally in the treatment of dysentery. Byssolity, bis-so-lite (Gr. busses, fine flax, klades, a branch), a name applied to fibrous varieties of amian-

thus, tremolite, actinolite, and other minerals of a fliamentous nature.

absent, or having as many petals as there are lobes to the calvx; stamens hypogynous, equal in number to the petals, and opposite to them, or twice as numerous. or indefinite (when more numerous than the petals some are always sterile); filaments more or less united anthers 2-celled, introrse (turned inwards); over sessile or stalked, composed of 4—10 carpels, united seasue or stated, composed of \$\frac{1}{2}\$ to carpets, united round a centreal column; style simple; stigmas equal in number to the carpels; ovules 2 in each cell fruit usually capsular; embryo straight or somewhat curved, usually lying in a small quantity of fleshy ablumen, the cotyledons being plaited or spiral. There are 45 genera and 400 species, mostly tropical plants. In their properties they closely resemble the Maloncea and Sterculiacea; thus, many are mucilaginous, as the Watheria douvadinho, the species of Pteropernume, and the bark of Guazuma ulmifolia, Abroma angustum, and Dombeya specialitis. The fruit of Guazuma ulmifolia contains a sweetish pulp, which is eaten in Brazil.

The most important plant of the order is Theobroma Cucao, the cacao or cocoa-tree, from the seeds of which cocoa and chocolate are prepared. (See TREOSHOMA.)
The typical gen. Byttneria does not include any plant remarkable for useful products.

BYANTINE ARCHITECTURE, be-zan'-time.—After the division of the empire of Bome into the Eastern and Western empires, the latter of which retained Kome as its capital, while Constantinople, then known as Byzantium, became the seat of government of the former, new styles of architecture were gradually produced in each metropolic to sait the requirements and progress of the age, which aprung out of the forms that had been adopted for the temples of heather Rome and the Christian churches of the later period of the empire. From the classic architecture, therefore, of old Rome was derived the Romanesque, which gradually apread through Western Europe, and is one sidered by some to have passed through various phases, known as Lombardic, Norman, Saxon, &c., until it

# Byzantine Architecture

attained the full extent of its development in the Gothic exchitecture of different periods in the Medicaval ages; and the Byzantine, the parent stock of Arabian architecture, from which all public buildings of ancient date in northern Africa and Spain derive their principal characteristic features, the pointed arch excepted, which influenced the architecture of the East, excepted, which indusined the architecture of the East, and even spread westwards, as may be seen in many a noble structure in Venice, Italy, and southern France. In our own times, Bysantine architecture is the ecclesistical style of architecture in Russis, the prevailing style of the Grack church, as Gothic architecture is seculiar to the cathedrals and churches of Roman Catholic and Protestant countries in Western and Catholic and Protestant countries in Western and central Europe. Byzantine architecture may be con-sidered to have been originated by Constantine the Great, who commenced rebuilding Byzantium in the year 324, and gave the city the hame which it now years, removing the scat of government thither from bears, removing the scat of government thither from Rome about four years later. Constantine spared no expense to make his new city the most magnificent in the world; public works of all kinds were erected with marvellous rapidity, from the designs of architects who had followed the emperor from Rome, and adorned with sculpture gathered from the fallen cities of Greece and Asia Minor. At first, the palaces, temples, churches, baths, and basilicas, which were crected, were based on the plans, and embraced all the characteristic features of similar buildings at Rome: but, to carry out his grand designs, Constantine caused schools to be established for the study of architecture, in which men were trained for the profession, who gradually mingled new and original features with those of the mingled new and original features with those of the style that had been introduced from the West, and formed a style of architecture peculiar in itself, and eminently adapted to the requirements of the ritual of the Greek church, although bearing evident traces of the source from which it originally sprung. There are four periods of Byzantine architecture, including are non periods of Byzantine architecture, including that of its decline, from the conquest of Constantinople by the Venetians in 1204, to the overthrow of the Eastern empire by the Turks in 1453. The first, or transition period, in which it gradually lost its similarity to the architecture of Rome, then known as Romanesque, ranges from 325 to 525. The churches were then built in the form of the Roman basilication. (see Basilica), with a central nave and long sideaisles, a portico at the western end, and an apse at the east end. The second period, when it had at the east end. The second period, when it had assumed an entirely distinctive character, extends from 525, shortly after which Justinian assumed the purple, to the close of the 8th century; and the third from this epoch to 1204, when Baldwin, count of Flauders, and his Venetian allies, attacked the Greeks, and gained temporary possession of Constantinople. The prevalent form of the churches of the second period, or period of pure Byzantine architecture, is that of the Greek cross; the central square, formed by the intersection of the arms of the cross, is covered by a dome or cupola, and the spaces which represent the arms are also covered by semi-cupolas, or, in many cases, entire ones. The whole length of the interior, from east to west, is divided into five parts. At the east end is the apse, in which stood the altar, divided east end is the apse, in which stood the alter, divided from the next portion, called the bems, by a panelled acreen richly adorned with paintings and gilded carred work, in which were three doors of communication be-tween the bems and the apse, which was considered to be the holiest part of the church. The bems or sametiary, which lay immediately before the apse, sometimes contained the bishop's throne. The choir came next, extending from the bema to the nave, and was allotted to the priests and those who took part in the chord services of the church. The pare formed the body of the church, separated from the choir by a halustrade, and from the narthex, or large western ves-tibule. by a screen. The narthex was provided with tibule, by a screen. The narthex was provided with galleries in which the female catechumens sat, the gameries in which the related exceptances sut, the males coupying the ground-floor of that portion of the building. The Roman, or semicircular arch, is the only form of arch employed, and the great distinctive fea-ture of the style is the constant use of the cupols or

# Byzantine Architecture

pierced with lights, which gave a light and alegant as pearance to that part of the structure. The heads at the windows were sensitivous in form. The door sometimes had semicircular headings, but they were generally surraounted by the flat lintel; the pillars use and analysis are constant of the pillars use that the pillars use the generally surmounted by the first intest; the pulsar users generally square or otagonal in form, surmound by square capitals taporing downwards, with the iners of the lower part of the capital taken of whe surmounted an octagonal shaft, to give it a corresponding form below, although the upper part remains aquare. The capitals were adorned with foliage, go rally of a symmetrical pattern, in relief, on sanks, panels formed in the faces. The interior was right ornamented with soulpture, painting, and means work of most elaborate description. The cathedral of St. Sophia, now the principal mosque at Constantinople, built by Justinian in 532, is considered to be one of the inest existing specimens of Byzantine architecture; good examples of the style of the second period are also to be seen in the churches of St. Sergius and St. Irene, at Constantinople. The best examples of the third period are the churches of St. Mark at Venice, and St. period are the courons of st. mark at venues, and ex-Pantocrator at Constantinople: in this period greater attention was paid to external decoration, but the churches were much smaller in every respect. The church of St. Anthony at Padua, the extendral at Akt-la-Chapelle, the churches of Revenue and Prise, and that la-Chapelle, the churches of Havenna and Fras, and that of St. Frant at Périgeaux, in France, are also Byzantine in character. Noble and massive in form, and decorated with broad masses of rich and warm colour, wast and majestic in its proportions, with all the details boldly, yet carefully and laboriously worked out. Byzantine architecture, in its purest character, as exemplified in the church of St. Sophia, the great type of the style, is well worthy of adoption in modern English church architecture: for while it will bear comparison church architecture; for, while it will bear comparison with Gothic architecture in every respect, and is superior to it in many, it is infinitely better than that of the classic form gathered from the heathen same of Greece and Rome, as may be seen by contrasting the magnificent Byzantine church built at Wilton, in Wiltshire, by the late Lord Herbert of Lea, better known as Mr. Sidney Herbert, with the heavy unpreposessing piles, in imitation of the classic style, that were produced by the architects of the 17th and 18th centuries. The following account of the church of St. Sophis, rebuilt by Justinian after it had twice suffered destruction by thre, is derived from the historian Gibbon. The architects were Anthemius of Tralles, and Isidorus of Miletus, the former of whom superintended the works in person, often accompanied by the emperor himself. It was finished in nearly six years from its commencement, and dedicated to the service of God by a sol festival. The eastern part of the dome was injured by an earthquake, and the dome was, therefore, rebuilt by the uppnew of Anthemius, under the direction of Ju-tinian. The dome is 115 feet in diameter, and lighted tinian. The dome is 115 feet in diameter, and lighted by 40 windows round the base; the first dome was very flat, being barely 20 feet in height, or 180 feet above that, being barely 20 feet in neight, or 180 feet above the pavement; the second dome, which still exists, is 40 feet high. The circle on which the dome rises is supported by four bold arches, which spring from massive piers of freestone, clamped together with iron and cemented with lead and quicklime, placed at the four angles of the central space; the dome is built of pumice stone and very light porous bricks from the isle of Rhodes. The form of the building is that of a Greek cross, measuring 269 feet from east to west, from the sanctuary to the nine western doors between the narthex and the nave, and 243 feet from north to south. The doors of the edifice are the only parts in it made of wood; the building itself is built of brick covered with elabs of marble. It is richly adorned with 100 columns of marble of different colours, issper, and porphyry; eight of which came from the Temple of the Sun, and eight, of green marble, were given by the magistrates of Ephesus. The walls, the great central dome, the or expresses. The waits, the great central dome, the semi-domes, and pavement, are adorned with mosaics; and there were many images of our Saviour, the Virgin Mary, and the saints, which the Turks have mutilated and defaced. Every part of the building was adorned with gold and silver; the balustrade of the choir, the capitals of the perarre, the ornaments of the doors and sallaries were of hunter withly silt; the dome, which was supported on erches of a wide span, choir, the capitals of the perare, the ornaments of the springing from massive piers at the four corners of the doors and galleries, were of bronze, richly gilt: the central space. The base of the dome was sometimes sanctuary is said to have contained more than 17 toss

# Byzantine Church

of silves, many portions of it being overlaid with solid plates of that metal; and the holy uses and vestments of the altar were of pure gold, enriched with jewels of great value. It is computed that the lowest sum which can be named as the cost of the building is one million pounds sterling.—Ref. Neale's History of the Roly Eastern Church; Ferguson's Hund-book of Architecture; English Cyclopadia—Arts and Sciences.

Brianking Churche opportune Arts and sciences.

Brianking Church comprehends collectively all those churches which acknowledge the supremacy of the commencal patriarch of Constantinople. The adherents of this church are comprised ulmost entirely within the limits of Turkey, Greece, and Palestine, and are altogether estimated to amount to about 3,000,000.

BYZANTINE, GREEK, OF EASTERN EMPIRE, are designations given to the Eastern Roman empire, sounded on the death of Theodosius the Great, a.D. 395. This monarch divided the Roman empire between his two sons, Arcadius and Honorius, giving to the former the eastern portion, comprising, in Asia, Svria, Asia Minor, and Pontus, to the shores of the Black Sea; in Africa, Egypt; in Europe, Thrace, Mœsia, Macedonia, Greece, and Crete. Through the weakness of Arcadius, this empire suffered many misfortunes. At first the government was in the hands of Rufinus, who was succeeded by the eunuch Eutropius, and the latter by Gainas, the murderer of Rufinas. This last fell in consequence of his ambitious designs in 401, and the proud and covetous empress Eudoxia now ruled till her death in 404. Her husband survived for four years more, and, on his death in 408, was succeeded by his son, Theodosius II.; but being a minor, and naturally of a weak and feeble mind, the government was conducted first by Anthemius and afterwards by his sister Pulcheria, who took the title of Augusta and governed with great ability. She enlarged the empire by wreating West Illyria from the Western empire, and Armenia from Persia. On the death of her brother, in 450, she succeeded to the empire, and married the senator Marcianus, whose valour averted the attacks of Attila on the frontiers. Lee I, a Thracian of low birth, was elevated to the throne on the death of Marcianus, in 457. He ruled well; but an expedition of his, undertaken against the Vandals in 467, failed. He was succeeded by his grandson, Leo II., in 474; but he only surgived a few months, and was followed by his father, Zeno. The rule of this monarch was by his father, Zeno. The rule of this monarch was weak, and he was disliked by his subjects. During his reign the empire was harassed not only by foreign foes was disturbed by internal rebellious. After his death, in 491, his widow Ariadne, by marrying the minister Anastasius, raised him to the throne. His reign was characterized by numerous wars. He carried on a six years' contest against the robber tribes of Mount Taurus; he was engaged in war with the Bulgarians on the Danube, to defend himself from whose neursions he built the long wall, as it is called, across incursions he built the long wall, as it is called, across the peninsuis of Coustantinople. The war with Parsis also broke out afresh during his reign. On his death, in 518, the soldiery proclaimed Justin emperor. This monarch maintained his position mainly through the influence of the clergy, whom he conciliated by persecuting the heretics. He was succeeded in 527 by his nephew Justinian, famous for his code of laws. His nephew Justinian, famous for his code of his san talk reign was distinguished by the victories of his generals Belisarius and Narses; but its rapid decay after his death showed how little had, during his reign, been contributed to the material strength of the empire. He was succeeded (665) by Justin II., a weak and cruel prince, under the government of his wife Sophia. The Lombards wrested from him a part of Italy; he carried on an unsuccessful war against the Persians; and the Averi plundered the provinces on the Danube. Vexation at these misfortunes drove him insane. Tiberius, cup-tain of the guard, was then made regent, and on the care of the guard, was then made regent, and on the death of Justin, in 578, he was raised to the throne. He reigned with mildness and wisdom, purchased peace with the Aver, and conquered the Persians through his general Mauricius, whom he left as his manessor in 582. The latter replaced Kosroes II. on the throne of Persia, and thus obtained peace with that country; but, on the exher hand, his wars with that country; but, on the exher hand, his wars with that Avani did not prosper. He was slain in a military taxari did not prosper. He was slain in a military taxari excessor, Phocas, proved a 288

# Byzantine Empire

wicked and abandoned ruler, and was clain in a cen-spiracy, 610. He was stocceded by Heracius, who was successful against the Avari and Persian, but found a more formidable foe in the Avabs, who during 695-41 overran the countries on the Enuhantes, Byris, and Egypt. Heraclius was succeeded by his son, Constantine III.; but he died soon after, and was suc-Constantine III.; but he died soon after, and was succeeded by his step-brother Heracilonas, who specific both is crown in an insurrection. Constant III. ascended the throne 612; he concluded a peace with the Arabs, but afterwards, in 608, lost his life in accomplinary. He was succeeded by his son, Constantine IV., Pogonatus, who compelled a peace from the Arabs by the Greek fire, but was, on the other hand, obliged to give tribute to the Bulgarians. He was succeeded in 695 by his son, Justinian II., who was deposed in 695 by Leontins, and he in turn by Apsimar, or Tiberius III., and this last by the Bulgarian king Trebelius, on which Justinian, in 765, again ascended the throne. He was assassinated in 711, and with him terminated the dynasassinated in 711, and with him terminated the dynasassinated in 711, and with him terminated the dynasty of Heracius. In 713, Philippicus, the successor of the last king, was deposed, and in 716 Anastasius, who succeeded him, retired to a monastery. His successor, Theodosius III., abdicated the following year, and Leo III. ascended the throne. In his contests with the Arabs he gave occasion for the breaking out of those conrent the empire for more than a century. In 728 the exarchate of Ravenna was lost, and the eastern provinces became the prey of the Arabs. His son, Constanting V., who succeeded him in 741, was a harge and arable property. was a brave and noble prince, but, on account of his zeal as an iconoclast, was hated by the monks, who gave him the surname of Copronymos. Lee IV. reigned from 775 to 780, and was succeeded by Constantine VI., who, having attempted to free himself from the influence of his mother, Irene, and her para-mour Stauratins, that ambitious woman caused him to be blinded, and he died soon after (797). A powerful party having risen against her, she was obliged to take refuge in a convent, and Nicephorus was raised to the throne (802). He fell in a war against the Bulgarians (811), and his son Stauratius soon lost the throne to (811), and his son Stauratus soon lost the turone to his brother-in-law, Michael I., who, in his turn, had to yield it up to his general, Leo V. (813). This last was a skilful and victorious ruler; but he fell in a conspiracy excited by his zeal against image-worship (820). Under Michael II, Crete and Sicily fell into the hands of the Arabs. His successor, Theophilus the hands of the Arabs. His successor, Theophilus (829-42), is praised for his love of justice. Under Michael III. (842-67), in 842, by the council of Nicas. the worship of images was again established. Basilius I., the Macedonian, who caused Michael III. to be put to desth, governed (867-86) with wisdom and power, and was rictorious over the Paulicians (whom power, and was rictorious over the Paulicians (whom see) and the Arabs. His dynasty continued in possession of the Byzantine throne, with few interruptions, till 1056. His son, Leo VI., surnamed the Philosopher, reigned from 886 to 912, and was succeeded by Constantine VII., Porphyrogenitus (912-58). The dissolute Romanus II. reigned from 959 to 963, and was succeeded by Nicephorus Phocas (963-69), and the latter by Tzimiskes, who ruled till 976. He was victorious against the Arabs and Bulgarians, as well as acquiret the Russians was for the first time. well as against the Russians, who, for the first time, during the reign of Michael III., appear in a hostile attitude towards the Byzantine empire. Basilius II. (976-1025), the son of Romanue, a brave prince, con-(976—1020), the son of Romanie, a prave prince, some queried the Bulgarians, and made their country a pro-vince of the empire. His successors, his brothers Con-stantine VIII. (1025-28) and Romanus III. (1028-34), who obtained the throne by marrying Zoe, the daughter of Constantine, were very unlike him. The latter was assassinated by his wife Zoe, an abandoned but crafty princess, who raised successively Michael IV. (1034), Michael V. (1041), and Constantine IX. (1043) to the throne. On the death of Constantine (1054), Theodorn, sister of Zoe, was raised to the throne, and Theodora, sister of Zoe, was raised to the surgue, sum on her death, in 1050, was succeeded by Michael VI., who, the following year, was deposed by Isaac I., with whom begins the Commenian dynasty. He retired to a monastery in 1059, and was succeeded by Constantine X., who reigned thi 1067; and his widow Endozia, by marrying Romanus IV., raf "I him to the throne.

Romanna was deposed by Michael VII., whose successors were Nicephorus III. (1078) and Alexius Comnenus (1061). Under the latter of these began the Crusades. His successors were Johannes, or Kalo-Johannes (1118), and Manuel I. (1143), both able Orusades. His successors were Johannes, or KaloJohannes (1118), and Manuel I. (1142), both able
princes, who warred successfully against the Turks.
Manuel's son, Alexius II. (1189), was mufdered by his
guardian Andronicus (1189), who son afterwards fell
man insurrection, and with him terminated the Comnenian dynasty. His successor, Isaac II. (1185), was
deposed by his brother, Alexius III. (1195); but the
Crusaders afterwards restored Isaac to the throne,
together with his son, Alexius IV. The cltisens, however, raised to the supreme power Nicolas Kanalas together with his son, Alexius IV.

ever, raised to the supreme power Nicolas Kanalas,
who took the title of Alexius V., and put to death
Alexius IV. In 1204 the French and Venetians took
Constantinople, as well as the European portion of the Sysantian empire, and founded, by raising Baldwin count of Flanders to the throne, the so-called Latin empire (1204-61). Baldwin died 1206, and his brother Henry reigned till 1216. He was succeeded by Peter, count of Auxerre and Courtensy, who reigned only a count of Auxerre and Courtensy, who reigned only a chart time and for the next for your the application. count of Auxerre and Conrienay, who reigned only a short time, and for the next four years the empire was without a ruler. In 1221 Robert, son of Peter, came to the throne, and was succeeded by John of Brienne (1228-37), and the latter by Baldwin II. (1237-61). During the reign of the last of these a great part of the Latin empire was taken possession of by Johannes Vatazes, the successor of Luscaris, who had founded a Greek empire at Nicma, in Asia Minor; and in 1261 his successor, Michael VIII., Palmologus, with the aid of the Genoese, took Coustantinople, and the Latin of the Gencese, took Constantinople, and the Latin empire thus fell. Michael was succeeded by Andronicus II. (1282), who, from 1322, was obliged to divide his power with Andronicus III., who became sole emhis power with Andronicus III., who became sole emperor in 1328. He died 1341, and under his successor, Johannes V. (1341-91), the Turks first obtained a firm footing in Europe. The sultan Murad, in 1361, took possession of Adrianople and made it the seat of government; and his successor, Bajazet, besieged Manuel II., the son of Johannes, in Constantinople itself. In 1422 the capital was a gain besieged by Murad II. Johannes VI. (1425-48), son of Manuel, was in 1444 compelled to pay tribute to the Turks. The last Byzantine emperor was Constantine XI., brother of Johannes. He struggled bravely, but in vain, against the overwhelming forces of the Turks, and at last fell heroically fighting in defence of Constanat last fell heroically fighting in defence of Constantinople, which was captured by Mohammed II., on the 29th May, 1453, and the Byzantino empire was brought to a close .- Ref. Brockhaus' Conversations Lexikon.

BYZANTINE HISTORIANS, is a name given to certain Greek writers who have written on the history of the Bysantine empire. They are divided into three classes:

—1. Those whose works refer exclusively to Byzantine history; 2, those who write on general history, treating also at some length of Byzantine history; and 3. those who have written on Byzantine architecture, antiquities, customs, &c. The works of the Byzantine historians were collected and published by Labbe, Fabrotti, Duffesne, and others, in 42 vols., Paris (1854—1711). A new edition of the Byzantine historians, entitled "Carpus Scriptorum Historiae Byzantine," was commenced at Rome, 1828, by Niebuhr, with the assistance of Bekker, Dindorf, Schopen, Meinecke, and others, and many volumes of it have since been published.

BYZANTINE PAINTING AND SCULPTURE.—Byzantine art may be considered as the connecting link between ancient and moderu art. When Constantine removed the seat of empire from Rome to Constantinople, many an artist that had gained repute in Rome sought to acquire an extension of renown in the new imperial city. There they founded a Byzantine school of art, to which the painters and sculptors of the West resorted when the savage hordes of the North poured over the sunny plains of Southern Europe, and gave the comp de grace to the waning power of the Western empire. In Byzantium, this school preserved the characteristics of ancient art during the sombre dawn of the Mediaval period, when the culture of the fine arts languished and almost died out in other parts of Europe, or became debased and devoid of spirit and beauty. It also struck out a new and original path in desilizing and representing with artistic force and

excellence, both with the pencil and the chiesl, graces and virtues of the Christian faith, in opposit to the efforts of the artists of ancient Greece and Ros to the cutter of the artists of ancient arresposant annual who skilluly expressed the attributes of heathenism. by portraying the perfection of the human form, animated indeed by human passions and desires, but nucontrolled and unsoftened by the elevating influence of that latiful the property of the controlled and unsoftened by the elevating influence of that latiful the property of the controlled and unsoftened by the elevating influence of that latiful the property of the controlled and the property of which they knew not, but the spirit and expression of which the Byzantine artists so thoroughly felt and comprehended. In both painting and sculpture, their works were executed in a careful and pains-taking manner; and mechanical perfection was attained in the manipulation of their subjects and the way in which the separate details were laboriously worked out. The influences of oriental climes and the recollections of ancient art met and mingled on common ground, and united in giving character and originality to the Byzantine school. Their figures are full of dignity; their form, attitude, and expression, betoken them as being conceived in a spirit truly Christian, while the accompany ing details were marked by a symbolism pregnant with meaning; as when the garments of our Saviour, resisting the Spirit of Evil in the hour of his temptation, are painted black, as typical of error and evil, and the Virgin Mary is represented with a black complexion. to signify the bitter woe that wrung that loving mother beart. Indeed, the principal fault in Byzantine art seems to lie in the manner in which its professors strove after perfection in detail, particularly that of a mechanical nature; but, on the other hand, this betokens a true love of art, and a desire to attain a translation in the aright narrawhich they took to becomens a true love of art, and a desire to attain excellence, in the evident care which they took to neglect nothing which might tend to give force or expression to their work. In mosaic-work the Byzantines excelled; the domes of their churches, as well as the pavements and the walls in parts, being beautifully inlaid in elaborate and exquisite tracery, often grotesque in form, glowing with brilliant colours. They possessed goldsmiths and jewellers of no mean order. who were animated by tastes and feelings truly artistic. as may be seen in the magnificent chalices, candelabra, and crosses of the Byzantine period, encrusted in many cases with jewels of great value, that have remained to our own times; they were also exceedingly skilfal in carving in ivory, and in the illumination of copies of the Holy Scriptures. Byzantine art retained its preminence until the close of the 12th century, when it gradually declined, until the conquest of the Eastern empire by the Turks ended the existence of the school that had flourished so long and so successfully. But it had done its work; its professors had carefully pre-served the traditions of bygone ages, and handed them, unimpaired by lapse of time, and accompanied by their unimpaired by lapse of time, and accompanied by their own experience and teaching, to the various schools of Italy, in which its influence may be plainly traced, particularly in those of Sienna and Florence, as exemplified in the painting of St. Peter and St. John, by Pierrolino (1100), in the Academy of Fine Arts of Sienna, and that of the Virgin and Child, by Guido di Ghezzo (1221), in the church of San Domenico, in the same city, and in many of the works of Cimabue, Giotto, and Leonardo da Vinci, who flourished at Florence at later partical a later period.

BYZANTINE RECENSION, is the name given to the text of the Greek New Testament as propagated within the limits of the patriarchate of Constantinople.

C. ·

C the third letter, and second consonant of our alphabet, bet, has two sounds, being pronounced like k before the rowels a, o, and u, and like s before e, i, and y. This letter is first met with in the Latin alphabet, where it occupies the same place as the gamma or g in the Greek; and, indeed, originally it had the same sound; legiones, with the earlier Komans, being written leciones. Subsequently the g sound became hardened to that of k, and that was the only pronunciation that it afterwards had with the Romans, as we know from the circumstance, that whenever the Greeks had occasion to adopt Latin words with c into their language, they always represented it by k; as Cleero, Kikero; Cæsur, Kaisar. As regards sound, C is a

#### Cleaha

sujections letter in English, as its place could always be supplied either by k or a. As a numeral, C stands for 100, CC for 200; and so on. In music it as the name of one of the notes of the gamut. Placed after the clef, it intimates that the nucic is in common time, which is either quick or slow as it is joined with allegre or adagto; but if alone, it is usually adagto. If the C be crossed or turned, the first requires the six to be alwayd quick the letter the requires the

ar to be played quick, the last very quick.

CAIRA. (See KAIRA.)

CAIRA. (See KAIRA.)

CAIRA RAO (Fr.), an abbreviation of the word cabriolet. It is a small light carriage for one horse, which generally plies for hire, although some gentlemen have private cabs of their own.

Cana, ku'-ba, a Jewish measure, the sixth part of a seah, or satum, and the eighteenth part of an ephah. It was equal to 31 pints of our wine measure, or 25

pints of our corn measure.

\*\*CABAL, kā-bal' (Fr. cabale), a number of persons united together for some secret design, usually to promote their own private views in church or state by intrigue. It differs from party as being usually by intrigue. It differs from party as Deing usuany composed of a few persons, and it generally implies secrecy and intrigues. In History, it is a name given to the ministry of Charles II., consisting of five men famous for their intrigues, and the initial letters of whose names form the word Cabal; viz., Clifford, Ashley, Buckingham, Arlington, and Lauderdale. "Never," says Hume, "was there a more dangerous ministry in England, nor any more noted for pernicions connects." cious counsels.

CABALLABIA, & db-bd-lai'-ri-a, in Middle-Age writers denotes lands held by the tenure of furnishing a horseman with suitable equipment during war, or when the lord had occasion for him.

CARRAGE. (See Brassica.)
CARRAGE. (See Brassica.)
CARRAGE BARK. (See Andira.)
CARRAGE FLIT, kibb-big (Anthomyte Brassice), an insect of the same gen. as the beet-fly and turnipfly. Its larva feed upon the roots of cabbage, and often do great injury. It is about a quarter of an inch long, and the expanse of its wings is about half an inch. The colour of the male and female is dark grey. The face of the male is silvery grey, with a dark streak on the forehead; the abdomen is linear, and the eyes nearly meet together on the crown of the bead. The face of the female is whiter than that of head. The face of the female is whiter than that of the male, and there is no dark streak on the forchead; the eyes are wide apart, and there is a broad black stripe between them; the abdomen of the female also terminates conically. The larver, which are yellowish-white in colour, closely resemble those of the common fiesh-fly.

CABBACH PALM, a name commonly given to a palm having a tender terminal bud, which is boiled and eaten as a vegetable. (See Abeca, Chamerors, Euterpe.) Cabbata, käb-öd-ü (Heb., traditions), is a term cometimes used in a large sense to denote all the

traditions which the Jews profess to have received from their fathers; in a more restricted sense, it is applied to a species of theology and philosophy made up of mystical interpretations and metaphysical speculations concerning the Deity and other beings, said to have been handed down by a secret tradition from the earliest ages. Some of the rubbins pretend that the origin of the Cabbala is to be referred to the angels, and that the angel Raziel instructed Adam in it. According to the Maimonides, God, when he delivered the law to Moses, gave him also the explanation of it. This explanation he communicated to Aaron and the elders, and it was afterwards handed down traditionally from father to son. In truth, these explanations of the law are only the interpretations and decisions of the gabbins on the law of Moses, in the framing of which they studied principally the combinations of particular more seamen principally the combinations of particular words, letters, and numbers, and by that means pre-tended to discover the true sense of the difficult passages of Scripture. The Cabbala is divided into the symbolical and the real. The former consists in seeking abstruse and mysterious significations in a word by attributing certain values or meanings to the to the symbolical, and comprehends doctrines, is divided into the theoretical and practical. The aim of the theoretical is to explain Scripture according to the Theoretical is to explain Scripture according to the Date of the best home, twisted very strongly and compactive. The general number of strands in a rope cable is three,

seemst traditions, and to form therefrom a philosophical system of metaphysics, physics, and manmatching. The practical, on the other hand, pretends to teach the art of performing miracles by an artificial application of the divine names and centences of Scripture. Some of the Jews believe that Jesus Christ wrought his miracles by virtue of the mysteries of the Cabbals. Carrianters, kiti-ba-lists, are those Jowish doctors who profess the study of the Cabbals. The first cabbalistic author that is known is Simon son of Joschai, who is said to have lived a little before the destruction of Jerusalem by Titus, and is the author of

struction of Jerusalem by Titus, and is the author of a book entitled "Zohar."

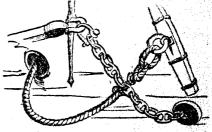

Cabin, kāb'-in (Fr. cubane), a term in Mar, used to denote certain apartments in a ship, designed for the In ships of use of either the officers or passengers. war there are several cabins, the principal of which (for the use of the chief officer) is called the state cabin, for the use of the cine officer is called very projecting and is furnished with a balcony or gallery, projecting over the stern. The apartments where the other officers sleep and mess are usually called berthe. In Virginia ginia, the habitations of the Indians are called cabina. They generally stand about nine or ten feet in height and are made by fixing poles in the ground and fasten-ing them together at the top; these poles are then covered with bark, a hole being left in the roof to carry off the smoke.

CABINET, kub'-i-net, denotes a closet or retired apartment; also a private room in which consultations are held. In the abode of a prince, the cabinet was an apartment where he transacted the business of the state, advised with his privy counsellors, and issued his decrees. Hence the name came to be applied to the counsellors chosen by monarchs to advise with them on the course of public affairs, and to direct the higher on the course of public mains, and to discountry, the branches of the administration. In this country, the privy council was formerly the adviser of the king in all weighty matters of state; but, by degrees, a selection of the members of this body came to be made by the king for more private advice, and at length, in the reign of William III., the distinction of the cabinet from the privy council, and the exclusion of the latter from all business of state, became fully established. The first lord of the treasury, the lord chancellor, chancellor, of the exclusion of the private and the state of the private of th cellor of the exchequer, president of the privy council, and the secretaries of state, now five in number. have always seats in the cabinet, and with them are usually associated nearly an equal number of their colleagues in the ministry, presiding over other important depart. ments of the government.

Cabini, kab'-e-re. the name given to mystical deities of antiquity venerated in Egypt, Phonicia, Asia Minor, and Greece, but of whose nature and functions little is known. In Greece, their rites were performed with great ceremony in Samothrace, Lemnos, and Imbros; in Asia Misor at Pergamus; in Phonicia at Berytus; and in Egypt at Memphis. Their names, number, character, and other particulars, are given so diversely by different authors, that little can be affirmed with certainty regarding them. The festivals celebrated in bonour of the Cabiri were called Cabiria.

in honour of the Cauri were cance consers.

Cable, kait'-! (Fr. Sp.).—This term is employed on board ship to denote either a large rope or a strong chain generally attached to the anchor. Rope cables, which

## Cabombacem

but some are made with four. The strength of a good shie six inches in diameter has been reckened to be equal to sixty tons. Chain cables, although they are much heavier and possess less elasticity than rope cables, are now very generally adopted in all classes of vessels. They are composed of iron links, the length of which is usually about is it diameters of the iron of which it is made, and the breadth about 34 diameters. or which is usually about six diameters of the iron of which it is made, and the breadth about 34 diameters. All chair cables made for the government are required to be manufactured in lengths of 124 fathoms. In the middle of every other length there must be a swivel, and in each length a joining-shackle. The links are made of bar iron, and the sizes of chain cables are denoted by the thickness of the bar iron used. Each link is bent into a nearly oval form, and is strengthaned. link is bent into a nearly oval form, and is strengthened

in the middle by a stay-pin of cast iron.

Cabondaces, kai-bom-bai-se-e, in Bot., the Water shield fam., a nat. ord. of plants in the class Dicotyledomes, sub-class Thalamifore,—aquatic plants with floating peltate leaves; sepals and petals 3 or 4, alternating with each other; stamens definite or numerous; thasame flattened, small; carpels 2 or more, distinct; frait indehiscent; seeds few; embryo minute, inclosed in a vitellus, and outside of abundant fleshy albumen. There are only two genera belonging to the order; namely, Cabomba and Hydropeltis. The species occur in America, Australia, and India; they have no important properties. Hydropeltie purpurea is said to be

nutritions CAROTZ, ka-boots', a name for the drug Koussoo. (See

BRATERA.)

CACAO, or COCOA. (See THROBROMA.) CACHALONG, kash'-ā-long, a tine variety of opal, found on the borders of the river Cach, in Bucharia. [See OPal.] A specimen from the Faroe Islands consisted of silica 95-32, water 3-47, and traces of iron, potash, soda, lime, and magnesia.

CACHALOT. (See Sperm Whale.)
CACHE, kash (Fr., a lurking-hole).—The settlers in the west of North America, when crossing over the Rocky Mountains, often find it advantageous to disburden themselves of some of the articles which they are carrying. In order that they may gain possession of them on their return, they are in the hubit of digging holes, in which they place the provisions or other arti-cles, and then cover the place up. These holes, or places of concealment, are called caches. The construction of a cache is a work of great ingenuity and labour. A hole six or eight feet deep, and several feet broad, is first dug; the articles to be concealed are then put in, and the hole is filled up, the surface being carefully replaced, so as to show no sign. Landmarks are, however, noted, and the locality of the cache is Landmarks easily found when the travellers return.

CACHET, LETTERS DE, kash'-ai, were secret warrants proceeding from, and signed by, the kings of France, and countersigned by a secretary of state, by which any person could be imprisoned or banished to a certain place without any reason being assigned. The introduc-tion of them is ascribed to the famous Capuchin Padre Joseph, under the ministry of Cardinal Richelieu. They were also called lettres closes, or scaled letters, to distinguish them from lettres patentes, or public docu-ments. During the reign of Louis XIV. lettres de sacket might be obtained by any one who had influence with the king or his ministers, and were frequently resorted to as a means of gratifying private revenge. During the reign of Louis XV, they were often given away to favourites as cartes blanches, with only the king's signature, so that any names might be inserted.

CACHERIA, kāk-ex'-i-ii (Gr. kukos, bad, hexis, habit), is a term used in Med. to denote a bad condition or habit of body, arising from whatever cause, in which the functions are imperfectly performed, and the com-plexion unhealthy. It is employed by Cullen to denote plexion unhealthy. It is employed by Cullen to denote a particular class of diseases in which the general habit is affected; and a change of complexion, with emaciation or morbid enlargement, are characteristic symptoms;

as, jaundice, dropey, &c.
Cactous, kdi-seek, the title given to the native chiefs
in some parts of America at the time of the conquest

by the Spaniards: it signifies "lord" or "master."

CACODEMON, kith-o-de-mon (Gr. kakos, bad, and suman, demon), denotes an evil or mischievous demon or epirit. (See Demon.)

# Caddice-worm

CACONT. £86'o-86 (C.H.As or Kd), sa a metallic base, containing areano. It is prepared its chloride by the action of zine. It is a thin, he chloride by the action of line. At it a lim, areas parent, colourless liquid, resembling arranted the discount of liquid, resembling arranted the pouree into oxygen, chlorine, or the air, it inflames. It boss at 338° Fahr., and crystallizes in large transparent square prisms when cooled down to 21° Fahr. At forms salts with the halogens and acids. It also forms an acid containing three equivalents of oxygen. This acid is peculiar as possessing no poisonous pro-perty, though containing nearly half its weight of arsenic.

CACCRINES, kak-o-e'-thes (Gr. kakes, bad, ethes, disposition), a bad custom, disposition, or habit; as the caccethes scribendi, the desire for acribbling. An incurable cancer is also called a cacoethes in medi-

CACOPHONY, kd-kef'-o-ne (Gr. kakes, bad, phone, voice, sound), in Grum., is a fault of style, consisting in the bringing together of two letters or syllables which produce a harsh or disagreeable sound, or in the too frequent repetition of the same letters or syllables,

CACTACER, kak-tai-se-e, in Bot., the Cactus or Indian Fig fam., a nat. ord. of plants belonging to the class Dicotyledones and the sub-class Calyciflore. The Cactuces are remarkable for their succulence, for the great development of their cellular tissue, and the anomalous forms of their stems, which are globular, columnar, flattened, or angular. Most of the species are leafless, having tufts of hairs or spines inste the senses, the flowers are sessile, sometimes very showy; the sepsis and petals are usually numerous, and scarcely distinguishable from each other. The stamens originate in the orifice of the tube formed by the originate in the orince of the tube formed by the combination of the petals and sepals, are very numerous, and consist of delicate thread-like fiaments terminated by small roundish authers. The overy, which, in consequence of its adhesion to the sepals, seems to occupy the place of the flower-stalk, consists of a single cell lined with nariotal placents or comments. of a single cell lined with parietal placentas, covered over with minute ovules; its style is slender, with stigmas equal in number to the placentas. The fruit is succulent, and contains a great number of seeds, which are without albumen. These plants are natives of the tropical regions of America. There are 18 genera and about 800 supposed species. Many 18 genera and about 800 supposed species vield edible fruit, useful in febrile complaints. Cattle feed on the succulent stems of some species during the dry season in certain districts of South America One plant belonging to the order is largely cultivated in Mexico for the nourishment of the cochineal insect; and numerous species are grown in European conservatories on account of their splendid flowers, or their

vatorics on account of their splendid flowers, or their singular forms. The most interesting species are described under the names of the genera to which they belong. (See CEREUS, BERNOGACTUS, OPUNTIA, PERESKIA.)

CACTUS, Käli-tus, the name under which Lännsens included the Cactacce, believing that they formed a single genus. The name still continues in popular use, being applied to any plant in the order. (See CACTACES.) The term appears to have been adopted from Theophrastus, who used it to describe a spiny plant. plant.

CADARI, or KADARI, kad-a'-re, a sect of Mohammedans, who assert free-will in opposition to fate, deny the existence of any secret power in determining the will, and reject all absolute decrees and predestination. The author of this sect was Mabed ben Kaled al Giho-

ni, who suffered martyrdom for his belief.

Caddice-worm, kad'-dis, the common name of the species of Phryganea which reside in the water in cases, which they form of various substances, such as bits of stick, grains of seed, small stones, &c., held together by a silken thread, secreted in their bodies in the same manner as in the silkworm. The perfect insect, the caddis-fly (Phryganea grandis), has a body of a leathery consistence, and thickly clothed with hair; shead small, with semi-globular eyes; antennas as long as the body; anterior wings elongated, lanceolate in the females, but rather more situes in the males. They are very active, moving with a gliding motion; but their flight is awkward. They frequent damp and marsby situations. When handled, they emit a very species of Phryganea which reside in the water in cases,

# Cadence

unpleasant odour. Their colours are ordinarily brown

or grey.

Capence, kail-dense (Fr. addence; Lat. cadens, from CADENCE, Kerl-dense (Fr. cadence; Lat. cadens, from cade, I fall), in Mus., a term signifying a fall or pause, either at the end of a piece, or at the termination of each of its parts. In vocal or instrumental music, cadences are used for the same purpose as stops in writing; i.e., to indicate the terminations, either of the parts into which a composition is divided, or the sunclusions of entire pieces; as in writing, stops mark the divisions, or completion of a sentence. There are two kinds of cadences,—viz., middle and all? the former, like commas and semicolons in writing, divide the various parts of a composition; whereas the latter denotes the conclusion of a piece.

CADET, MILITARY, kil-det (Fr. cadet, vounger in

Theress the latter denotes the concussion of a piece.

Cader, Military, kà'-det' (Fr. cadet, younger in service), a youth who is trained up for the army by a source of military study and discipline. When the friends of any youth intended for the army wish to give him a sound military education, they enter his name at the Cadets' College. There they supply him with board, lodging, clothing, books, and instruments. The annual expense thus entailed varies from £100 to £20. The age of admission is between 16 and 19, and the subjects of study are English composition, modern languages, mathematics, natural and experithern languages, mathematics, natural and experimental sciences, history, geography, and drawing. Every student can go up for examination in any hulf-year and the results of the examination are reported to the commander-in-chief. As soon as vacancies occur in the college, they are filled up by the candidates in the order of merit. After being entered, they study for two years a great variety of subjects connected with theoretical and practical military art. When this course of study is complete, the cadets are eligible for commissions in the army, a certain number of which are at the disposal of the college. Queen's cadets are the sons of officers who have fallen in action or have died from the effects of active service, and have left their families in reduced circumstances. They are twenty in number, and are admitted and educated gratuitously. When the East-India Comeducated gratuitously. When the East-India Company possessed both military and political power in India, upwards of 5,000 officers were in their pay. The sompany established a college or school at Addiscombe, where youths were examined as to their proficiency in an ordinary English education. If they passed sutinfactorily, they were admitted into the college. The lage of admission was between 14 and 18. After two was a study in the college of the passed sutinfactorily and the superior of the second s years' study in the college, they became cadets in the years study in the conject, they oceans cates in the company's service, receiving pay and being eligible for service in India. Thus the officers who commanded the company's regiments had been educated by the company. The introduction of competition in the matter of appointments to the college, and the transference of the powers of the company to the crown, have greatly modified this class of military cadets. The word cadet is also applied to any younger member of a noble family, in order to distinguish him from the eldest son, and in France to any junior officer, in con-

tradistinction to one who is his superior.

CADET, NAVAL, an officer of the lowest rank in the British navy. On being appointed to a ship, every captain is permitted to nominate one cadet; and every fing-officer on receiving his flag can appoint two. The first lord of the Admiralty appoints all the rest, who are subjected to competitive examination. The candidates, who enter the service at the age of 12 to 14, are examined at the Royal Naval College at Portsmouth. If they pass their examination in a satisfactory manner, they are sent to a training ship at Plymouth or Ports. mouth, in order to learn seamanship, &c. If they do not make sufficient progress at this stage, they are rejected; but if they give satisfaction, they are put on board sea-going vessels. Here they are expected to note care-fully all that is going on; to salute the officers, and to learn the different ways of splicing ropes, tying knots, arranging the rigging, going aloft, keeping watch, &c. The cudet becomes a midshipman after serving satisfactority three months in a training ship and afteen

months in a sea-going ship.

Cant, or Kant, ka'-de, ds a Turkish word signifying some learned in the law, one who decides in judicial sators and matters, a judge. The cadi is an inferior judge, and is raids. It established in the towns and villages; while the mollah,

## Cadveeus

or apperior judge, is over a province. Both are chosen from the higher ranks of the priesthood, as all law is founded on the Koran.

CADIZADELITES, kai-diz-of-de-lites, a sect of Moham-medans, who resemble the ancient Stoics, assuming an uncommon gravity of manner and avoiding all feature and amusements. They receive both the Bible and the Koran, assimilate in many things to the Christians, and believe that Mohammed was the Holy Ghost whom Christ said was to be sent.

Christ said was to be sent.

CADMENT LETTERS, kidl-me-an, the name given
to the sixteen letters that originally composed the
Greek alphabet, and which, according to tradition,
were brought by Cadmus from Phonoicia, whence they
were called grammata Kadmeia, Cudmean letters. In reality, they are found to agree, in form and order, with the Samaritan or Phonician letters.

Cadmium, kud'-me-um (symbol Cd, equivalent 56 74, spec. grav. 8 6).—Cadmium was first discovered in 1818, by Stromeyer, in small quantities in certain zine ores, in consequence of the behaviour of their solutions with sulphuretted hydrogen. It is occasionally found in nature as a sulphide in zinc ores, and is obtained as an accidental product during the extraction of that metal. Being much more volatile than zinc, the first portions of the distilled metal contain a large proportion of cadmium. It is separated from the zinc by means of canmum. It is separated in our and white colour, much resembling tin in its physical properties. It is soft, malleable, and ductile, and when bent emits a creaking sound, like tin. It is easily fused, and distils at a high temperature. When heated in air, it oxidizes more temperature. readily than zine, burning with a luminous flame, and producing a reddish-brown oxide. It fuses at 442° Fahr, and by slow cooling may be obtained in beautiful octahedral crystals. When heated in dilute hydrochloric or sulphuric acid, it evolves bydrogen. hydrochloric or sulphuric scid, it evolves bydrogen it only forms one oxide, CdO, which is formed when cadmium is heated in air. It is yellow, brown, or black, according to the temperature to which it has been exposed. It is infusible, does not volatilize, and forms well-marked saits with the acids. The chloride is formed by dissolving the metal in hydrochloric scid. It crystallizes in four-sided prisms. The sulphide, which is obtained by heating a mixture of oxide of cadmium and sulphur, is much used as a pigment. It is of a bright yellow colour, but becomes temporarily is of a bright yellow colour, but becomes temporarily red on being heated. The only other important salt is the iodide, which has of late received an important application in photography. Being a very stable salt, it is not decomposed when added to collodion. For this reason, collodion indized with it preserves its sensitiveness undiminished during many months. For photographic purposes, it should be purchased at a respectable chemist's, as it is a salt that is very difficult to prepare for oneself.

CADRITES, kad-ri'-tees, a kind of Mohammedan monks named after their founder, Abdul Cadri. They live together in monasteries, which, however, they may quit when they please and marry, on condition of wearing black buttons on their garrents, to distinguish them from the rest of the people.

Caduceus, kā-du'-se-us, in Antiq., was the winged staff or sceptre of Mercury, said to have been presented to him by Apollo in return for the sevenharp etringed which Mercury given to had bim. Amongst the ancient Greeks and Romans, the caduceus was the staff of office borne by ambassadors and he-

MARCURY REARING CADUCANA

cumstance, doubtless, that it become a symbol of Marcury, the messenger of the gods. Originally, it was a simple olive-branch; then a white or gilded staff, round which was added in a later age the representation of two twisted snakes, with two outstaticked wines above them. Many mythological representation of two twisted anakes, with two out-stratched wings above them. Many mythological legends are connected with the addition of the enakes. One tale relates that Mercury with his caduceus sepa-rated two anakes that were lighting. Hence the wand began to be the symbol of peacemaking, and the figures of the serpents were retained. The Roman sent to the Carthaginians a measenger bearing a esduceus and a javelin; thus offering them the choice of peace or war: and in old Roman coins Mars is often of peace or war; and in old Roman coins Mars is often represented with the caduceus in one hand and a javelin in the other. Mercury was considered to be the patron of commerce, and the rod of the caduceus signified power, the serpents prudence, and the wings diligence. It is still used in modern times as the symbol or representative of commerce.

symbol or representative of commerce.

Caddoos, ki-du'-kus (probably from caduc, fleeting, frail), in Bot., falling early or soon after development. Thus, a calvx is said to be caducous when it falls off before the flower expands, as in the poppy.

CECUM, se'-kum (Lat. cacus, blind), in Anat., is the dame given to a large blind-pouch, or cul-de-suc, and the pairs of the commencement of the

extending downwards from the commencement of the

extending downwards from the commendation of the large intestine. (See Intestines).

CAEN STONE, kan(g), in Geol., an colitic limestone, so termed from its being extensively quarried in the neighbourhood of Caen, in Normandy. It is the French representative of our Great, or Bath solitic. It forms an admirable building-stone; for though it is

It forms an admirable building stone; for though it is soft in the quarry, it hardens on exposure, and is found by be exceedingly durable.

CESALPINIA, se-zāl-più-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-i-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-i-a, (so named in honour of CESALPINIA, se-zāl-più-i-a, (so named in hon America and Asis, having pinnate or bipinnate leaves, showy yellow flowers, and stems which are usually more or less prickly. The useful products of the genus are snowy yearow howers, are the serial products of the genus are very numerous. The valuable dye-wood known in commerce as Brazil-wood, is said to be obtained from the species C. crista. It is used for dyeing red, rose-colour, and yellow. Braziletto-wood, which produces the state of the serial to come from C. braziletto-wood which produces the serial serial to come from C. braziletto-wood which produces the serial serial to come from C. braziletto-wood which produces the serial serial to come from C. braziletto-wood which produces the serial serial serial to come from C. braziletto-wood which produces the serial serial serial to come from C. braziletto-wood which produces the serial fine red and orange tints, is said to come from C. brame rea and orange time, research wood, which is extensively used for dyeing red or peach-colour, is probably the produce of *C. echinata*. The exact species yielding these three dye-woods have not, however, as yielding these turee dye-woods have not, however, as yet, been determined with certainty. Another valuable dye-stuff, also giving a red colour, is obtained from the Asiatic species C. suppan, and is known as Sappan, Bookum, or Bukkum-wood. The roots of this tree, under the names of Sappan, and is known as Sappan, and the roots of this tree, under the names of Sappan-root and yellow-wood, are under the names of Sappan-root and yellow-wood, are sometimes imported from Singapore, and employed for dyeing yellow. The twisted legumes of C. coriaria are powerfully astringent, and are extensively used in tanning. In commerce they are known as Divi-divi, or Libi-dibi pods. The legumes of C. Papai, the Pi-pi of commerce, are employed for similar purposes, but they are very inferior to them. The roots of C. moriand and upon are said to be diurctic, and the wood of ge and nuge are said to be diuretic, and the wood of C. echinate is stated to possess tonic properties. From C. eleosperms an oil is obtained.

C. geacoperms at on is obtained.

C. Exalivitine, see-e, in Bot., a sub-ord, of
the Leguminosa, or Bean am., characterized by irregular
flowers, which are not penilionaceous, and by the petals
being imbricated in the bud, with the upper or odd
petal inside the leteral ones. The genera belong to the warm regions of the globe, and some of the species the warm regions of the globe, and some of the species the locust-trees for example—grow to a prodigious size. (See HYMENEA.) Among the products of this suborder useful to man, are many valuable dye-woods; such as Brazil-wood (Casalpinia), logwood (Hamatoxylon), and barwood (Haphia); many excellent kinds of timber; some important medicines, as sensa (Cassia), and balsam of Copais (Copaijera); edible fruits, as the tamarinds (Tamarindus, Codarium), and halsam of Copain (Casalpinia). (Cassia), and balsam of Copails (Copailsra); edible The flercer animals were conveyed in iron cages. Wild fruits, as the tamarinds (Tamarindus, Codarium), and balsam of Ceratonia); tanning substances, fibres, and gums.

CRSAM, se'-car, a title borne by all the emperors of the carbot keep in the carbot control of the carbot contr

and greatest Cassar, the title Augustus Cass given to the reigning emperor, and that of C the heir-apparent.

the herr-apparent.

OEBSHAN OFRENTON, se-ray-re-on [Lat. come, from ondo, I cut), in Surg., is the extraction of a child from the womb by an incision through the parietes of the abdomen and the uterus. It is also called hydrocross, from hustera, the womb, and tome, a section. This operation has been practised from very ancient times, and persons so extracted were termed organize. Julius Casar is said to have received his name from his have been throught into the wold in this way. ing been brought into the world in this way. There are three cases in which this operation may be necessary:

1. When the fectus is alive and the mother dead, either in labour or in the last two months of pregnancy; 2. when the fœtus is dead but cannot be delivered in the usual way, on account of the deformity of the mother, or the disproportionate size of the child; 3. when both mother and child are alive, but delivery cannot take place, from any of the above causes. The operation is one of great danger, but there are many instances of both mother and child having lived after its perform-

Castus, sees'-tus (Lat.), in Antiq., a rough gaundlet made of raw hide, and strengthened with lead or plates of raw inde, and strengthened with the project of iron. It was used by the wrestlers both to protect their hands and wrists, and to give force to their blows. The crestus was also a kind of girdle made of wool, which the husband untied for his bride

The first evening after marriage.

CESURA, ec.su'-ra (Lat. cado, I cut), in Greek and
Latin poetry denotes the cutting off of the last syllable Datin poerly denotes the entering out the assignment of a word from those that precede it, and carrying it forward into another foot. It always renders the syllable on which it falls long, though it may properly be short. In modern poetry it denotes the passes which is introduced into a verse or line to render the versification more melodious, and to aid the recital

CETERIS PARISUS, se'-te-ris par'-i-bus (Lat., other things being alike or equal), is a term frequently employed by mathematicians and philosophers to denote the equality of all other points or circumstances except the equanty of an other points of circumstances except those at issue; as when it is said that the velocity and quantity of blood circulating in a given time through any section of an artery will, caterie paribus, be ac-cording to its dismeter and its nearness to, or distance from, the heart.

CAFFRINE, Or THEINE, kaffeen' (C. H. N.O.).
a crystalline alkaloid found in tea, coffee, Paraguay
tea, and in guarana, a species of chocolate prepared
from the fruit of the Paullinia sorbites. Tea contains from 2 to 4 per cent. of caffeine, coffee but 1 per cent. It is easily obtained from tea by making a strong infu-It is easily obtained from tea by making a strong infusion of the leaves, mixing it with subsectate of lead, which precipitates the tamin, and transmitting a current of sulphuretted hydrogen through the liquid to precipitate the excess of lead. On evaporating the solution, and allowing it to cool, the caffeine crystallizes out in long silky needles. It has a weak, hitter tasts, and fuses at 352°. Water and alcohol dissolve but a small quantity in cold, but it is very soluble in boiling water and ether. The fact that caffeine forms the essential principle of three substances used by widely different nations is a very curious one. and widely different nations is a very curious one, and shows that the craving which it satisfies is as natural as it is universal. The use of tea or coffee as an article of diet seems to exercise a very important influence in retarding the waste in the tissues of the body. Its effect on the human system has, however, yet to be fully studied.

CAFFIRS. (See KAFFIRS.)

CAFFRE-BREAD. (See ENCEPHALARTOS.) CAGE, kaij (Fr. cage), an inclosure made of boards, or with lattice-work of wood, wicker, or wire, for confining birds or beasts. Beasts were generally brought to Rome, in ancient times, shut up in cages made of oak, or beech, ingeniously formed, and covered with green boughs, in order that the animals might be deceived and fancy that they were still in their forest

#### Catanagam

tain essemblies; as those of the clergy, the states general, &c.

CATRACAM, or KAIRACAN, beil-mel-ken, a dignity in the Ottoman empire answering to that of lieutenant, stenant-governor, among us. There are usually two Caimecams, one residing at Constantinople, as th governor; the other attending the grand vizier in the quality of lieutenant. Sometimes there is a third at-

tending the grand signior.

Carmozoro, kain-o-so'-ik (Gr. kainos, recent, soc, life) a Geol, a term applied to the upper stratified systems selding recent forms of life, as distinguished from Meossic (holding intermediate), and Pulsozoic (holding section and extinct forms). The oninozoic period emconsists and extinct forms). The caincoin period embraces the tertiary and post-tertiary systems of British cologists. (See Grology.)

Caintres, kain-ites, a perverse and stupid sect of hereties that arose in the 2nd century, and took their name from Cain, whom they reckoned worthy of special.

conour. All the wicked persons mentioned in they looked upon with favour; even Judas Is carlot, whom they regarded as worthy of praise from having caused the death of Christ, and thereby saved the world.

"CA IBA, sa e'-ra (Fr., it will go on), is the name given from the refrain to a well-known song, by which, during the first French revolution, the lower classes were inflamed and incited to deeds of crucky. The famous Marseillaise was directed against the foreign, and the ra ira against the aristocrats, the domestic, enemics of the revolution.

"Ah, ça ira, ça ira, ça ira ! Les aristocrates à la lanterne!"

The melody is older than the words, having been a favourite air with queen Marie Antoinette.

CAIRN, kairn, is a word of Celtic origin, denoting a heap or pile of stones. The term is commonly applied to the artificial piles of stones, usually of a conical form, that are to be met with in various districts. They appear to have been raised for various purposes, as to distinguish marches or boundaries stinguish marches or boundaries, to commemorate battles; but, most commonly, they were intended to mark the burial-places of distinguished individuals. The bones found in cairus are generally half-burned, and are inclosed in cists, or stone chests, or in urns of earthenware. In one case, as many as seventeen stone chests were found under the same cairn .- (Pennant.) Various articles in common use, as flint arrow-heads. stone hammers, &c., or ornaments, are frequently found along with the bones. The size of these cairus is believed to have been, in general, in proportion to the rank or popularity of the deceased; for, not only would the people of the district assemble to testify their respect to him, but, so long as the memory of him existed, not a passenger went by without adding a stone to the heap. "To this moment," says Pennant, "a suppliant will tell his patron curri mi cloch er do charne (I will add a stone to your cairn), meaning, when you see no more, I will do all possible honour to your memory." Some of the larger carns are communication, have internal galleries, or chambers. The most remarkable of this class is at New Grange, near Drogmarkance or unis cases is at New Grange, near Drog-heda, in Ireland. Cairns belong chiefly to stony countries; where stones are acarce, earthen tumuli take their place. They are to be found throughout the British islands, in France (especially Brittauy), and Norway; but in Germany, Denmark, Sweden, and other parts of Europe, tumuli are more common.

CAIRMOOM, or CAIRMOORUM, kairm-form, a smoky-tinted variety of quartz, often of a fine brown or amber colour. It receives its name from the mountain Cairngorm, on the sides of which it is found in great perfection. It is sometimes so dark as to be marry black. It is much used for seals, brooches, and the larger forms of jewellery; and one Ediuburgh lapidary is said to have cut nearly £400 worth from a single

Crystal.

Carsson, kais'-son (Fr. caisson, a chest), a term applied in Civ. Eag. to large frameworks of timber, used plied in Civ. Eag. to targe transewors or a bridge, or in forming a foundation for the piers of a bridge, or any structure, a portion of which is built in deep water. Casseons are now only used for this purpose in cases where the bottom is rocky, as it has been found that the underlying strate, if of a different nature, are apt 894

# Calenus

to be undermined and worn away by the action of the to be undermined and work away by the action of size water, to the detriment of the superstructure; as in the case of old Westminster bridge, the foundations of which were made in this manner in 1740, by Labeleye, a Swiss engineer, and which has been lately replaced by the present structure. The following was the method adopted:—When the bottom had been prepared and labeled a belief framing was the method scoped.—When the bottom had been prepared and levelled, a hollow framing was brought ever the spot, and, as soon as a sufficient quantity of masonry had been piled upon it, it was pierced and sunk. Caissons are now made open at both ends, and filled cansons are now made open at both ends, and filled with concrete, to insure solidity. Docks are sometimes closed by caisson-gates, especially if it is not necessary to open them very often. In Mar, the caisson is a machine for raising vessels, resembling an enormous chest, with an air-tight chamber in the interior, which will not allow it to which believe agants in dank it. will not allow it to sink below a certain depth. In order to raise the vessel, it is sunk, by letting the water into it, and brought under the ship's bottom, and there seems to be a superior of the same that the same that it is not that it is not the same that it is not the same that it is not cured. The holes, through which the water entered, are then closed, and the water pumped out. This causes it to rise and lift the vessel, bringing the bottom out of the water for inspection and repairs, which can be thus effected without bringing the vessel into dock, or hauling her on shore. In Mil., it is applied to the tumbril, or waggon, in which ammunition is carried; and to a large wooden chest filled with powder and shells, and buried under, or near, any fortifications, to

be exploded, if necessary, like a mine.

CAITHNESS FLAGS, koith-ness', in Geol., a series of dark-coloured flaggy beds, belonging to the middle portion of the Old Red Sandstone as developed in Scotland. These bods are rich in fossil fishes. The stone is of The stone is of great toughness and durability, and is largely employed

for paving.

CATUS COLLEGE (keys), Cambridge, or more properly, Gonville and Caius College, was founded in 1348, by Edmund Gonville, rector of Terrington, in Norfolk, and endowed for a master and three fellows. Various benefactors afterwards added to its endow-ments, and in 1558, John Caius, M.D., having rebuilt a large part of the college, and endowed three additional fellowships and twenty scholarships, obtained a royal charter, by which the former foundations were all con firmed, and his own foundation established, the name of the coilege to be, thenceforward, Gonville and Caius College. New statues have been given under act of parliament, 19 & 20 Vict. c. SS, by which the college is henceforth to cousist of a master, thirty fellows, and thirty-six scholars. The fellowships are all open, and are not vacated by marriage, but terminate, in general, at the end of ten years from the full standing of M.A. They may, however, be retained under certain circumstances and, if the fellow be holding, or have held, certain university or college offices, or shall have taken holy orders within five years after attaining the standing of M.A., or shall have been permitted, by special vote of the master and fellows, to retain it. Twelve of the fellows are seniors, the other eighteen are juniors. They are to be chosen from graduates of the college (ar, if the master and seniors shall at any time seafit, of th university) who have distinguished themselves in the studies of the university, or in some department of science, literature, or art. The thirty-six scholarships are divided into four classes, of different value, from £60 to £20, and are perfectly open. They are tenable until the scholars are of standing to take the degree of B.A., and may, in special cases, be continued until the holder is of standing to take M.A. There are also connected with this college four studentships in medicine. founded by Christopher Tancred, Esq., each of the annual value of £113, which may be held for three years after taking B.M.; two scholarships, of the annual value of £52. 10s., founded in 1830, by John Sayer, and in the presentation of the governors of Harrow school; and two exhibitions at Harrow school founded by John Lyon, 1890, each £10 yearly, for four years.—Ref. Cambridge University Calendar.

CAJANUS, kāj'-d-nus (from the Malsyname Catjang),

in Bot., a gen. of plants belonging to the nat. ord. Leguminose, sub-ord. Popilionaces. The species yield a kind of pulse, known as pigeou-peas, much used for food by the poor of the West Indies. In Jamaics. pigeons are usually fed with these seeds; hence their English name.

# Cajaput

Cararut. (See Malateuca.) Unlanden, kal-d-bash' (Sp. calabasa), a name given to vessels made from the hard shell of the fruit of

CALABASHES

the calabash-tree. These are much used on the West Indies and tropical parts of America, and serve as buttles. cups, goblets, &c., for holding liquids. They are often elaborately carved. and ornamented with various colours. The cala-bash will sustain a

considerable amount of heat, and it is sometimes used Dried gourd-shells, used as a kettle for boiling water. Dried gourd-s

for holding fluids, are also called calabashes.

CALABASH. (See CERSCENTIA.)

CALABUM, Rall-ai'-di-um, in Bot., a gen. of plants belonging to the nat. ord. Araceæ. The species are mostly natives of South America and the West Indies, and are frequently cultivated as stove-plants in this country for the sake of their elegant spotted stems and neat leaves. They have the same general appearance ness leaves. They have the same general appearance as the species of Arum, and resemble them in being all more or less acrid. The species C. sequinum is highly poisonous, and when any part is chewed, the tongue swells so much that the power of speech is lost. On this account, it has received the popular name of dumb area. C. scalifications the Brazil achieva is dumb-cane. C. sagittifolium, the Brazil cabbage, is cultivated in many parts of the world for its leaves and root-stock, which, when boiled, are edible. The leaves are preferred, and are said to form a most nutritious and delicate vegetable. The corms of many other species, when cooked, are edible.

CALAMANDER-WOOD. (See DIOSPYROS.)

CALAMINE, kall-a-mine, native carbonate of zinc. (See ZINC.)

CALAMINE, ELECTRIC, a cilicate of zinc, found in various parts of America in rhombic prisms and in massive incrusted aggregations. On being heated, it possesses electric properties : whence its name. It is

an important ore of zinc. (See Zinc.)
Calamintha, kál-a-min'-tha (Gr. kalos, beautiful, mintha, mint), in Bot., a gen. of plants be-longing to the nat. ord. Labiatæ. Four species are natives of Britain, and are known respectively by the trivial names of mountain-balm, cat-mint, basil-balm, and wild basil. The first, which is also termed the common calamint (C. officinalis), has aromatic leaves, which are frequently employed by country people to make herb-tea, and as a pectoral medicine.

CALASTEES, kāž-ā-miles (Lat. calamus, a reed), in Geol., fossil stems occurring abundantly in the conmessures. They are hollow-jointed cylinders, with longitudinal furrows, and their flattened condition proves that they must have been so soft as to offer little resistance to pressure. The true affinities of the gigantic plants, of which these are the remains, have

not yet been determined.

CALAMUS, kal'-a-mus (Lat., from Gr. kalamos, a stalk, stem, or reed), a pen made from a reed, probably the stem of Arundo Donax, used by the ancients. The reed-pen, called Kalam by the Arabs, is still commonly

employed in Oriental countries.

CALAMUS, in Bot., a gen. of palms consisting of numerous species, all having very slender stems, which are found climbing over the trees in the forests of the hotter parts of the East Indies. Some of the best descriptions of walking causes are obtained from the plants of this genus. The Malacca cane is the produce of C. Zaluaca; Rattan cane, of C. scipionum and re-dentum; and Partridge cane, of an undetermined species. The fruit of C. Draco is the chief source of the natringent resinous substance known in commerce as dragon's blood. This completely covers the fruit, and is melted or scraped off, and then formed into small cakes.

mali cakes. Calamus Aromaticus, *d-ro-māt'-i-kus*, a name given by the accients to a plant generally supposed to be the sweet flag. (See Acceus.) Dr. Royle is, however, of

## Calcareous Waters

opinion that the name was applied to the sweet-torn grass which he has designated Andropogon calamins ations. (See ANDROPOGON.)

CALAMUS SCRIPTORIUS, scrip-to'-ri-us (Lat., a w ing-pea), in Anat., is a groove or canal with a pea-like termination at the bottom of the fourth ventricle of

the brain.

CALANDRA, kill-in's drd, a gen. of coleopterous insects closely allied to the Circulionide. The corn-west (C. granaria) is included in this genus. In its perfect form this little beetle is of a reddish-brown colour, sbout an eighth of an inch long; has a sleader snout slightly bent downwards, a closely-panetured and very long thorax, and furrowed wing-covers, that do not entirely cover the tip of the abdomen; It bores halving the paneture of the abdomen; It bores have the provided the provided with the provided ao not enturely cover the tip of the abdomen. It boxes a hole into the grain with its proboses, in which an egg is deposited. The egg turns into a tiny grub, which devours the whole inside of the grain, leaving the husk entire. Wheat and other grain may, therefore, be much damaged without presenting a had appearance. If the true state of the case, however, should be suspected, there is a very simple test. A handful of the suspected grain is thrown into a pan of water. of the suspected grain is thrown into a pan of water, when the hollow husks at once float on the surface, and the sound grains sink to the bottom. It will afford some idea of the formidable character of these tiny beetles, to state as an ascertained fact, that one female is capable of producing six thousand of her kind in a single year.

Calappa, or Box-cran, käi-läp'-pü, a gen. of Crus-facea inhabiting the sens of the Indian Archipelage, the Pacific and Atlantic oceans, and the sens of South America. One of this family (Calappa granulata) is an inhabitant of the Mediterranean, and, according to Prisse, is found most frequently in the fissures of rocks. at a depth sometimes of a thousand feet. Their general colour is pale rose, with whitish feet and brown

nails.

CALASH, käl-äsh' (Fr. calèche), a small low-wheeled carriage or chariot, employed for taking exercise in parks, gardens, &c. It is generally provided with a hood, or covering, which can be raised or drawn down at the pleasure of the occupant. The term calsah is also given to a head-covering used by ladies.

CALATRUS, kall-al-lines, a gen. of coleopterous insects belonging to the Geodephaya section. Upwards of twenty of this species of ground-beetle are found in

Europe.

CALATRAVA, ORDER OF, käl-ä-tra'-vä, an order of knighthood founded by the Abbe Raymond, after the knighthood founded by the Abbé Raymond, after the rules of the Cistercians, in 1158, when Sancho III., king of Castile, transferred to him the city of Calatrava. In 1163, the knights, under Don Garcias de Heddi, separated themselves from the monks, and were afterwards confirmed by the pope. In 1197, Calatrava was taken by the Moors, and the knights transferred their seat to the castle of Salvatierra, and called themselves after it. After the death of their twenty-ninth grand master, De Padilla, 1486, the choice fell several times upon the king, and in 1523 the pope made the office of grand master hereditary to the crown, and allowed the knights to marry. Though long one of the most honourable and distinguished of the orders in Spain, they never attained to great wealth, but they were possessed of great influence in the state. The order has lost most of its possessions, and, at present, is little more than an order of rank. The robe of the order is a white mantle with a red The robe of the order is a white mantle with a red cross of lilies on the left breast.

CALCAIRE-GROSSIEE, kul-kuire gros'-se-ai (Fr., coarse limestone), in Gool, an important member of the Eccane group of beds in the Paris basin, usually co-ordinated with the Barton, Bagahot, and Bracklesham

beds of England.

Calcarre-Silicieux, sil-e'-se-u(r) (Fr., flinty lime-stone), in Geol., a compact silicious limestone, which sometimes takes the place of the Calcaire-grossier in the Paris basin.

Paris basin.
CALCARBOUS SPAR. (See CALCITE.)
CALCARBOUS TUFA, kāl-kai'-ri-us-tu'-fa.—Calcareous
tufa is formed in volcanic districts by the deposition of
calcareous matter in a most or less compact form.
CALCARBOUS WATERS.—Carbonate of lime dissolves in pure water to the extent of two or those
grains to the gallon; but when carbonic acid is pre-

sent, it is much more freely taken up. If, however, the temperature be raised, the carbonic acid escapes, leaving behind a crystalline deposit of carbonate of lime. In nature, snormous crystalline concretions of this kind are formed by water charged with carbonic soid percolating calcareous strata. The stalactite carerus of Derbyshire are instances of this Kindare for Derbyshire are instances of this carbonic soid and carbonate of lime dripping from the roof, and leaving behind a portion of carbonate of lime before it drops. When it falls on the floor of the swars, another deposition of calcareous matter takes places, forming a statagmite, which gradually rises to meet the stalactite above it; in this way a natural pillar is formed. Most spring water contains carbonate of lime held in solution, which is deposited on the sides of the vessel when the carbonic acid is expelled by heat. In steam boilers this becomes a great inconvenience, and is obviated by adding sal-ammoniae to the water. Chloride of calcium is formed, which remains dissolved, while the carbonate of ammonia is volatilized with the steam. Water containing carbonate of lime in solution, or hard water, as it is popularly termed, is therefore softened by means of boiling. Hard water precipitates soap as stearate and margarate fines, forming the well-known curdy precipitate. Until the whole of the lime is thrown down, no lather can be formed; hard water is, therefore, very uneconomical for washing purposes. Dr. T. Clark has derised a very ingenious method of softening hard water, by adding milk of lime. The carbonic acid mites with the lime, setting free the carbonate originally dissolved, and the whole falls to the bottom as a precipitate of carbonate of lime.

CALCEDONY, or CHALCEDONY, kāl-sed'-o-ne (from Calcedon, in Bithynia), a translucent massive variety of quartz, closely allied to opal and agate, and often found associated with them. It often occurs in cavities in amygdaloid and other rocks, in the form of "icicles," or stalactites. The colours vary from white to yellowish brown, pale grey, bluish grey, and light

CALCECLA, kill-se-o'-Li (Lat., a little shoe), in Gool., a fossil brachiopod, so called from its under valve, which is shaped like the point of a shoe, and fitted with a lid-like upper valve. It is characteristic of the middle Devonian period.

CLECOLARIA. kāl-se-o-lai'-re-ii (Lat. calceola, a little shoe), in Bot., a gen. of herbaceous or shrubby plants belonging to the nat. ord. Scrophulariacez, and distinguished by the following cheracters:—Calvx 4-partite; oorolla 2-lipped, the lower lip being inflated so as to form a bag, and the shape of the whole, in some species, resembling that of a slipper; fruit a capsule, semi-bivalular, with bifid valves; only two fertile stamens. The species are natives of South America and the Falkland Islands. In Chili and Peru they occur in auch shundance as to give a peculiar aspect to the landscape. Most of them have corymbs of showy flowers, generally yellow, but sometimes purple. Calceolarias have been extensively cultivated in Europe as greenhouse plants since about 1830, and by crossing the species some lovely hybrids have been produced. Some of the species are used in South America for

OLICIES, kill-sine' (Lat. calx, lime), a chemical term, signifying the separation of the more volatile portions of a solid body by means of heat. Thus lime is formed from chalk or limestone by calcination. The older chemists applied the term to the oxidation of metals by heat, thinking it was an analogous process to that just mentioned; they therefore called alloxides produced by heat, calx, or calces of the metal; thus, calx of tin is what is now called oxide of tin.

CALCINITES, kall-sin-ites, compact calcareous ingrigistations formed in the open air. A section shows layers and lines of varying colour and hardness, which mark the gradual progress of the deposit.

CALOTTE, CALOAREOUS STAR, or CARBONATE OF LINE, till-site, institue crystallized carbonate of lime, commrsing under nearly 600 different crystalline forms, all derived from the fundamental rhombohedron. The purest crystals are transparent and colouriess; other varieties are semi-transparent and opaque, often co-domed with grey, red, yellow, rose, and violet. One

transparent form occurring in rhombuhedral drystals possesses the property of double refraction; i.e., chjects seen through it appear double. From having been found in Iceland, it is called Iceland Spar (which

CALCIUM, half-se-um (symbol Ca, equivalent 20, spec-grav. 1-55), the metallic base of the alkaline earth lime. Calcium belongs to the second group of metals, and has for its analogues barium, stroutium, and mag-nesium (which see). It is one of the most abundant nesium (which see). It is one of the most abundant substances in nature, forming a very large portion of the crust of the earth. It occurs in nature in combination with fluorine as fluor spar, with oxygen and carbonic acid as chalk, limestone, and marble, and with oxygen and sulphuric acid as gypsum, which is hydrated sulphate of lime. Calcium was first obtained by Sir Humphrey Davy by electrolysis, in 1808; but little Sir Humphrey Davy by electrolysis, in 1803; but little was known of its properties until Dr. Matthiesea formed it by the electrolytic decomposition of a mixture of the chlorides of calcium and strontisms. It is a light-yellow metal, of the colour of gold alloyed with silver; it is rather harder than lead. It melts at a red heat, and is very mulleable. It tarrishes in a day a trace again the red in melts at a red heat, and is very mulleable. It tarrishes in a day a trace again to day in meister. nishes in a day or two even in dry air, and in moister air it becomes slowly oxidized. It burns with a brilliant white light when heated in air, chlorine, or the vapours of iodine, bromine, and sulphur, and rapidly decomposes even at ordinary temperatures. It has also been obtained by MM. Liès-Boudart and Jobin by acting on iodide of calcium with sodium. The best-known compound of calcium is its oxide, or lime, which may be obtained in a state of perfect purity by heating pure carbonate of lime to redness. In practice, lime is made by burning common limestone with alternate layers of coal in a kiln. Lime is a white, porous, opaque, inodorous, infusible substance, with strong alkaline and caustre properties. When water is thrown on it, an equivalent is absorbed, and heat evolved, hydrate of lime (CaOHO) being the result. Hydrate of lime is commonly called slaked, or slacked lime, to distinguish it from anhydrous oxide, which is known by the name of quick lime, from its powerful caustic properties. Cold water dissolves about vio of its weight of hydrate of lime, forming lime-water. Contrary to the usual rule of solutions, hot water only contrary to the usual rule of solutions, hot water only dissolves about half that quantity. In fact, when lime-water, prepared in the cold, is heated, it deposits crystals, which redissolve as the solution cools. Limewater is alkaline to the taste, and turns vegetable yellows brown, and blues green. Exposed to the air, it gradually absorbs carbonic acid, and deposits carbonate for the Advances. bonate of lime. Milk of lime is bydrate of lime mixed with water until a milky fluid is obtained. Lime is greatly used in the arts for mortar, cement, and manure, for dyeing, soap-making, and leather-dressing. Mortar is prepared by mixing one part of freship slaked lime and two or three parts of sand, with suffleient water to form them into a paste. The theory of the hardening of mortar is but imperfectly understood, the most prevailing idea being, that a combina-tion of silicate of lime and a compound of the carbonate with the hydrate are formed, which, together, set in a solid mass. Hydraulic mortars, or cements, are such as set under water. They are made from natural or artificial mixtures of silics, or some earthy silicate, and lime. They are prepared by calcining a limestone and lime. They are prepared by calcining a limeatone containing these ingredients. A double silicate of lime and magnesis is formed, which has the property of absorbing water, and becoming insoluble. (For the theory of the action of lime as a manure, see MANURE.) Hydrate of lime is used in the purification of gas, in the preparation of summonia and bleaching-powder, in candle-making, soap-boiling, cotton-printing, tanning, and sugar-refluing. In the laboratory, hydrate of lime is extremely useful in preparing caustic alkalies, and in absorbing carbonic scid, for which it possesses a very strong affinity. In medicine, lime-water is used as an antacid, and to afford a supply of lime to the bones of rickety children who have not the power of assimilisting rickety children who have not the power of assimilating sufficient lime from their ordinary food to give the necessary compactness to their bones. The principal lime (CaCCo<sub>3</sub>).—This substance enters largely into the composition of rocks and minerals. In the smorphous state, it occurs abundantly under the well-known form

# Calcium, Chloride of

of limestone, colite, chalk, and mar!. It also forms the larger portion of corals, the bones of animals, the egg-shells of birds, the scales of fishes, and the shells of mollusks. In minute granular crystals, combined with various metallic oxides or bituminous matter, it constivarious metable of different sorts. White Carrars marble is nearly chemical, pure carbonate of lime. In a regular crystalline state, it occurs under a greater variety of forms than any other mineral. Its primary form is a rhombohedron, as in Iceland spar; but in arragonite it forms hexagonal and square prisms. (For a more particular description of these forms see Calcurs and ICELAND SPAR.) The uses of carbonate of lime are very numerous, under the forms of limestone and colite, which constitute building stone, marble, chalk, lithographic stone, &c. &c. When burnt with access of air, limestone forms ordinary lime; if, however, the air be excluded, and the heat raised to a considerable height, it fuses without undergoing decomposition, and, on cooling, forms a crystalline mass resembling marble. Chloride of line is the name given to bleaching-powder, which is prepared by passing a current of chlorine through milk of lime, by which means it is obtained insolution; or by passing chlorine over hydrate of lime, which produces it in the form of a moist powder. The product obtained is regarded by chemists as a mixture of chloride of calcium (CaCl) and hypochlorite of lime (CaO.ClO). By exposure to the air, hypochlorous acid is continually evolved by the action of the carbonio acid. If an excess of any acid is added, chlorine is produced. The former property is taken advantage of to destroy the gaseous poisons with which the air of sick-rooms and other localities is contaminated. By the action of the carbonic said of the sir, or by the addition of small portions of dilute sulpharic acid, hypochlorous acid is evolved, which oxidizes and destroys the miasmata. A mistaken notion has arisen that it is the chlorine that acts in this case; but, from the rationale given above, it will be seen that it is the oxygen of the hypochlorous acid which is the destroying agent. When chlorine is required for bleaching purposes, an excess of acid is used. (See BLEAGHING.) Chloride of lime is often used in the laboratory in conjunction with a weak acid as an oxidizing agent. Some chemists look on chloride of lime as being an oxychloride of calcium, or CaOCI, and deny that the compound contains chloride of calcium in an uncombined state, as none is dissolved out when chloride of lime is mixed with alcohol. Phosphates of lime.—There are several phosphates of lime, the most important of which is that obtained from the incineration of bones, which may be regarded as a triphosphate of lime. Superphosphate of lime, much used as a manure, is prepared by gradually mixing bone-dust with oil of vitriol, and adding an equal quantity of water between each addition of The mass is allowed to lie in a heap until it is dry, and is then used under the name of superphosphate of lime. Its real composition is found to be a mixture of time. Its real composition is found to be a mixture of phosphate and sulphate of lime with the animal matter of bones. Sulphate of lime occurs in nature as gypsum, selenite, and anhydrate. Gypsum, on being burnt, vields a white powder, commonly known as plaster of Paris, then is anydrous authorite of lime, possesses the property of soliditying when mixed with water: it also expands alightly at the same time. These properties render it extremely valuable for custing and moulding objects of which copies are required. Plaster of Paris absorbs water from the air if allowed to remain in unclosed water from the air if allowed to remain in unclosed (See Gyrsum and Stucco.) Sulphate of Hime is prepared by passing sulphurous acid through water containing chalk or hydrate of lime in a fine state of division. It is used as a convenient source of

CALCIUM, CHLORIDE OF (CaCI).—Chloride of calcium may be obtained from the residue remaining in the retort, after the preparation of ammonia, by adding to it a slight excess of hydrochloric acid and evaporating. On cooling the solution deposits crystals containing six atoms of water of crystallization. These crystals, which are six-sided prisms, are highly deliquescent. By fusing at a heat not exceeding 3/12° Fabr., four aquivalents of water are expelled, and the remaining white porous mass is extremely useful in the labora-

sulphurous acid.

## Calculating Machines

tory for drying gases. Further fasion expels the whole of the water. Anhydrous chloride of calcluing, on being mixed with water, gives rise to a considerable cleration of temperature; while the crystallized of hydrated salt, mixed with anow or water, depresses the temperature to -82° Fahr. Chloride of calcium is found in nearly all mineral waters. Chloride of palcium absorbs ammoniacal gas to a considerable extent. producing a salt of the formula CaCl.4NH ...

CALCIUM, FLUORIDE OF (CAF).—Fluoride of calcium occurs somewhat abundantly in the mineral kingdom as fluor spar, which is generally associated with the ores of tin, lead, copper, and zinc. It is found in crystals, the primitive form of which is the cube. They are generally yellow or purple, and sometimes pale green, or even colourless. On being heated, they decustitute violently, and emit a peculiar bluish-green phosphorescent light, which is probably due to electricity. Fluoride of calcium is sparingly soluble in water. It is soluble to some extent in uitric and bydrochloric acids, from which ammonia precipitates it unchanged. Sulphuric acid decomposes it, forming sulphate of lime with the evolution of hydrofluoria acid. It is principally used in the laboratory for this latter purpose. It is also employed as a flux in coppersmelting.

smelting.

Calcium, Phosphide of (Ca<sub>2</sub>P).—Phosphorus and calcium unite to form this compound, which is interesting as the source of the phosphides of hydrogen. It is prepared by distilling phosphorus over lime heated to low redness, a mixture of phosphide of lime and phosphate of calcium being the result. Phosphide of calcium is a dull red substance, hard enough to strike fire with steel. When powdered and exposed to the air, it slacks, emitting phosphuretted hydrogen. In its unslacked form, it is decomposed when thrown into water, phosphuretted hydrogen being evolved, which ignites spontaneously. ignites spontaneously.

CALCIUM, SULPHIDES OF. There are several com-pounds of calcium with sulphur, the principal of which are the protosulphide, which is known by the name of

Canton's phosphorus, and the pentasulphide.

Calcium, Teroxide of (CaO<sub>3</sub>).—This compound was procured by Thonard in brilliant crystalline plates. by adding lime-water to peroxide of hydrogen.

CALCULATING-MACHINES, kall-ku-lai-ting, machine by which all the common arithmetical operations and others of a more complex nature may be readily effected, thereby saving a considerable amount of time to those who are engaged in calculating long series of figures, and insuring results which cannot fail to be orrect. The system of logarithms (see Logaritms), invented by the celebrated Napier of Mcrchiston, in 1614, which is of the greatest assistance to mathematicians and others in the computation of figures, by shortening the ordinary operations, seems to have been instrumental in directing attention to the construction of an instrument by which arithmetical results could be produced by mechanical means, although the abacus (see Anacus) had been long used in Europe and Asia for effecting calculations; and Napier himself had produced what may be termed an elementary calculations. culating-machine, consisting of rods with four faces, known as Napier's Bones. (See NAPIER'S BONES.) The first instrument which can justly be called a calthe maximum which can justly operated a cat-culating machine was invented by Blaise Pascal, in 1642, when he was about nineteen years of age. It was more especially contrived for the calculation of sums of money, although it would also perform the ordinary operations of arithmetic with numbers on the common or decimal scale of notation. It consisted of a set of cylinders, with numbers marked on their external surface, moving on axles to which wheels were attached, with a certain number of notches cut in their circumference. As it is a matter of extreme difficulty to understand the construction and operation of a conplex calculating-machine from description only, it has been thought better to render the manner in which Pascal's machine was made, and the method by which it was worked, as clear as possible to the reader, merely mentioning the machines of other inventors, with a brief account of their general principles and purpose. Pascal's machine consists, as has been said, of a number of cylinders of the same size, with figures on the circumference, arranged in cortain

## Calculating Machines

series, as in fig. 1. In these figures, for the sake of exhibiting the whole of the numbers, the circumferences of the cylinders are represented as bands the extremities of which would join each other is the extremuses of which would join each other in brought into a circular form, at ax, yy, &c. It will be seen that the cylinder next the right hand of the reader is divided into twelve equal parts, equivalent to the number of pence in a shilling; the second into twenty parts, the number of shillings in a pound; while those towards the left hand, in succession, are divided into ten parts, corresponding to the nine figures and cipher used in our common system of notation.
With the cylinders last named, if there be a sufficient
number of them, the operations of addition and subtraction in abstract numbers can be readily performed,

# Calculating Machines

its circumference, one with twenty notches on the axie of the next, and wheels with ten notches on the axies of the remaining cylinders. These wheels are turned by hand with a small rod of metal, one end of which can be easily inserted in the notches, to pull the wheels for-wards, and each wheel acts on the one next to it, from right to left, by a mechanical arrangement, so that while the first wheel moves round once, the second moves onwards a twelfth part of its circumference; while the second moves round once, the third moves onwards a twentieth part of its circumference; and while each of the others completes an entire revolution, the one next to it, to the left, moves onwards a teach part of its circumference, for reasons that are sufficiently obvious, or which, at all events, will be clearly seen presently. It should also be mentioned, that in fig. 1 the whoels are placed, with the ciphers of each series in a line in front of the machine, ready to commence operations. The double lines merely represent the front of the machine, to which the requisite line of figures must be brought when it is desired to make any calculations, and against which the results should appear, to be conveniently read. For the sake of illustration, suppose it is desired to add £5. 13s. 2d. to £9. 14s. 11d. We must first turn the wheels by the metal rod, in the direction shown by the arrow, until the figures 0, 14, 11, appear in the front of the machine, as in columns  $x_2, y_3, x_4$  in fig. 2; the figures in column rr remaining unaltered. It will be noticed, that by the change of position from fig. 1 to fig. 2, the space now in front of the cylinder xx in fig. 2 has been moved onwards eleven divisions from its original position in fig. 1, in the direction indicated by the arrow. We must now move it forwards two spaces in the same direction, as we have to add 2 to 11; we then have 1 in the lower part of the space now in front, as in Bg 3, which indicates 1s. 1d., as the cylinder has moved forwards thirteen spaces, or a complete revolution and one space (representing a shilling and a penny) from its original position in fig. 1. But while the cylinder x x moves through one revolution, the wheelwork connecting it with the cylinder y y, causes that cylinder to move onwards  $x_0^{i,j}(t)$  part of its circumference, and the figure 15 appears instead of 14 (or would appear if figures were given, showing the successive action of each cylinder on that next it to the left, which the reader can easily construct for himself), which shows that Is, has been curried, as it were, to 11; and we have now to add 13 to 15 for the shillings, instead of 13 to 14. The cylinder y y must, therefore, be moved onwards in the same direction as before for thirteen spaces. which brings S in the lower part of the space in from: of the machine, indicating £1. Ss. as the result of the addition, as the cylinder yy has moved forward twenty-eight spaces, or one revolution, and eight spaces, from its original position in fig. 1. The cylinder  $xx_1$  from the action of the wheelwork connecting it with yy, has moved forward one space during the complete revolution of y y, bringing 0 in the lower part of the space now in front of the machine instead of 9, showing that £1 has been carried to the original £9, and indicating that the £5 to be added must be added to £10. The cylinder z z is, therefore, moved forward five spaces, which brings 5 in the lower part of the space now in front of the machine, and by the connecting wheelwork between the cylinders zz, rr, the latter is moved forwards one space from its original position in fig. 1, in consequence of xx having performed a complete revolution, giving the reading £15. 8s. 1d. as the result, as shown in fig. 3. It will be noticed that the lower figures in the spaces are the figures used in the operation of addition; the upper figures are used to perform subtraction. From the above process the general principles of calculating-machines will be un derstood, and it will be readily seen how machines of a simple nature can be constructed to perform opera-tions in compound addition and subtraction for any system of weights and measures. Machines of a more rsys rsys rsys rsys rsys complicated nature, that would require pages of a more complicated nature, that would require pages of a acription to make their construction and principles even faintly comprehended, have been invented by Thomas of Colmar, Staffel, Wertheimer, Barmowskir, and pence, can be added and subtracted. It should be remarked, that a wheel is attached to the axle of the cylinder on the right, having twelve notches in 388.

Calculus

Colendar

by him the Difference Machine and the Analytical Machine, are the most extraordinary. The former is yet causing, are sig most extraordinary. The former is yet incomplete, and is deposited in the museum of King's College, London. It was invented in 1822, or, rather, Mr. Babbage had then conceived the primary idea of the machine. Government assisted Mr. Babbage to carry out his invention by grants amounting to £17,000; but covernment aid was ultimately withdrawn in carragovernment sid was ultimately withdrawn in conse-quence of some quarrel between Mr. Babbage and the authorities, and the machine was thrown on one side. authorities, and the machine was thrown on one side.
It was intended to connect a printing or stamping apparatus with the machine, by which it would have registered the results obtained on copper plates. Had this invaluable machine been finished, it would have performed any operation in arithmetic and algebra, and complex processes of differentiation and integra-tion. The withdrawal of the government grant did not deter Mr. Balbage from prosecuting his plans, and he was an exhibitor of his inventions in the Indus trial Exhibition of 1862. The invention of the brothers Scheutz was based on the description of Mr. Bubbage's Schentz was based on the description of Mr. Babbage's Difference Machine, and is similar to it in general principles, though it differs from it in some points in the method adopted in its construction. It was purchased by Mr. Rathbone, a merchant of Albany, U.S., for £1,000, and presented by him to the Dudley Observatory in that town. Messrs. Schoutz have since completed a machine for the British government.— Ref. Edinburgh Review, July, 1854; English Cyclopæ-

CALCULUS, käll-ku-lus (Lat., dim. from calx, a lime-stone), in Med., is a hard inorganic concretion formed in various parts of the animal body, and bearing a in various perts of the animal cody, and pearing a general resemblance in form or composition to stone. It receives various names, from the parts in which it exists; its, salivary in the salivary glands and ducts, pulmonary in the lungs, intestinal in the stomach or intestinal canal, bilitary in the gall-bladder, surioury in the bidder, suriously in the interior. the kidneys or bladder, gouty in the joints of gouty persons. The most familiar instance of the formation persons. The most familiar instance of the formation of calculus is the tartar which is deposited from the saliva and mucus of the mouth upon the teeth. The term calculus is, however, most frequently applied to those concretions which are formed in the gall-bladder or biliary ducts, and those formed in the kidneys or bladder. Biliary calculi, or gall-stones, are composed almost entirely of cholesterine, with some colouring matter. They vary greatly in size and number, amounting sometimes to hundreds, and even, it is said, to thousands; but so long as they remain in the bladder they do not usually cause much uneasiness. It is when they pass into the canal by which the bile is conwhen they pass into the canal by which the bit is con-reyed to the duodenum, that they occasion great pain and derangement of the system. The pain occurs in parxysms, and is generally attended with shivering and vomiting. If the bile be wholly obstructed, jaun-dice comes on, and rapid emaciation succeeds. The disorder sometimes proves fatal, but generally the disorder sometimes proves ratio, our generacy are stones find their way, sooner or later, into the intestines, and the disturbance subsides. The best remedies are opium and hot applications over the seat of pain, or a warm ball. Urisany calcult, graved, or stone in the bladder, are concretions formed and existing in is the standar, are contentions formed and existing in the urinary passages. They generally originate in the kidneys, and afterwards pass down into the hiddeder, where they frequently attain a very large size: some have been found to attain a weight of 14 to 18 oz., and even more. While in the kidneys they are termed read catculi, and they sometimes remain there per-manently, and may even attain a considerable size without causing much inconvenience; but they may also produce inflatmation and abscess, and ultimately cause death. Generally, however, while yet of small size, they pass down the ureters into the bladder. Sometimes the passing is attended with symptoms similar to those occasioned by the passing of a gallsimilar to those occasioned by the passing of a gall-stone, and similar remedies are to be had recourse to. The calculus having passed into the bladder, is then termed a vesical calculus. At first it is attended with comparatively little pain; but unless removed or eva-cuated, it is sure to enlarge, and to give rise to one of the most dreadful diseases that are an afflict humanity. In the carlier stages much may be done to check the progress of this dangerous malady; but when the cal-culus is once formed, the only means by which it can

200

be got rid of is an operation. The stone must eithe be withdrawn through the urethra by an instrument or it must be broken into fragments small enou to be veided with the urine, or it must be extrac by an incision. (See LITHOTRITT, LITHOTORY.)
different varieties of urinary calculus are thus ch by Dr. Wollaston, in the order of their frequency :-1. Uric acid; 2. oxalate of lime, called the mulberry calculus from its dark colour and rough surface; 3. ammoniace-magnesian phosphate, called also the trip phosphate; 4. phosphate of lime, or bone-earth cal-culus; 5. fusible calculus, a combination of the last two species, and so called from its fusibility under the blowpipe; 6, the mixed calculus, composed of several of the other kinds confusedly mixed; 7, wrate of smmonia; 8. carbonate of lime; 9. cystic exide; 10. xanthio exide. The three last are extremely rare many of the calculi, and, indeed, most of them, are not of one uniform composition, but consist of strates of two or three varieties, one forming a nucleus for the other deposits, and calculi thus formed receiving the name of alternating. Uric acid is more common as a nucleus than any other substance. Urinary calculus is more frequent in some districts than others, and locality likewise influences the species of the stone. It is particularly prevalent in Norwich, while there are other large towns in which it is searcely heard of. In some families it appears to be hereditary, and especially in those who are also subject to attacks of gout. cially in those who are also subject to attacks of gout. It is much more common among males than females; and soldiers and sailors are particularly free from it.

The predisposing causes of it, however, are still very imperfectly understood.

CALCULUS, in Math., is a term generally applied to signify any brunch of mathematics which may lead to signify any branch of mathematics which may lead to or involve calculation,—in fact, to all except pure geometry. There is the common Arithmetical calculus, and there is the Algebraic calculus. The invention of the Differential calculus and the Integral calculus is claimed for Leibnitz; they are identical with the Fluxionary calculus invented by Newton. The calculus of Partial Differences is a branch of the differential and integral calculus; and the calculus of Variations is another portion of the same theory. That part of Algebra which relates to exponents and logarithms is sometimes called the Ernonential calculus.

is sometimes called the Exponential calculus.

CALDARIUM. (See BATH.)
CALDARIUM. (See BATH.)
CALDHON, kawl'-dron (Fr. chauldron), a large kitchen
vessel, generally made of copper, having a movable
iron bandle, by which it can be suspended on a hook

above the fire.

CALEDONIA, kill-e-do'-ni-d, the name given by the Romans to that part of Scotland lying north of the firths of Clyde and Forth, which formed the northern boundars of the Roman province Britannia, as established by Agricola, who penetrated farthest in this direction. The derivation of the term is doubtful, but the root, caled, or caledon, is evidently British. With direction. The derivation of the term is doubtful, but the root, caled, or caledon, is evidently British. With later writers, Caledonia corresponds pretty nearly with the present limits of Scotland. The inhabitants are described as having red hair and large limbs; as living in tents, naked and barefooted; as fighting from chariots, with shields and short spears, and having daggers also. They belonged not to the Germanic but the Celtic race. the Celtic race.

CALEDONIES, kal-e'-do-nite (from Caledonia,

land), a compound of sulphate of lead with the car bonnies of copper and lead, found in long prismatic crystals, of a deep bluish-green colour, at the Lead-

hills mine, in Scotland.

CALEMBOUR, or CALEMBOURG, käll-em-boor, is a French expression for a pun, said to have been taken from a certain Westphalian, Count Calemberg, who visited Paris in the reign of Louis XV., and became notorious for his blunders in the language.

notorious for his blunders in the language.

CALENDAR, or KALENDAR, kall-en-der (Gr. kalein, to call), a written catalogue or table of all the days of the year, arranged in the order of days and weeks, to which are generally added certain astronomical indications, such as the hours of the rising and setting of the sun, the entrance of that star into each sign of the sodisc, the commencement of the seasons, the phases of the moon, as well as the particular epochs of religious and civil acts. The calendar being in reality but the and civil acts. The calendar being in reality but the chronological table of the year, has necessarily varied

with different peoples, according to the divers forms of their year. These different forms will be found ex-plained in the article Yuak. The most remarkable calen-darsare,—1. The Hebrew calendar. They car of the Jews was a lunar one, being composed of 354 days, divided into twelve months, which had alternately twenty-nine and thirty days. In order to make this lunar year accord and thirty days. In order to make this funity ear accord with the solar year, the Hebrews supplied, seven times in nineteen years, an intercalary month of twenty-nine days. Each month was divided into periods of seven days, or weeks, the Saturday being celebrated under the name of Sabbath.—2. The calendar of the Greeks, whose year was likewise lunar, and composed of twelve months in a paternately twenty-nine and thirty was the saturday of the calendar of the contraction and thirty was the saturday of the calendar of the contraction and thirty was the contraction of the calendar of th souths, containing alternately twenty-nine and thirty Greeks added every two years a supplementary month. Back month was divided into three decades.—3. The Roman, or Julian calendar. The Roman pear, under Roman, or Julian calendar. The Roman year, under Roman, however, the year was extended to whelve months, or 355 days; but, although nominally thus defined, the calendar did not in reslity fix anything more precise than the commencement of the months and extended to the months. and seasons; and through the ignorance or negligence of the priests, the utmost derangement subsequently To obviate this confusion, Julius Casar, arose. To obviate this confusion, Julius Casar, in 46 s.c., effected a reform, by the introduction of the Julian calendar, in which the length of the solar year was fixed at 365 days, to which was added, every four years, a day called bissextile. This calendar was adopted not only by the Romans but also by all the modern nations, and remained in use until the introduction of the calendar of Gregory XIII. The Roman year had twelve months, each being divided into unequal parts by the Calenda, Nones, and Idea (see these words).—4. The Gregorian calendar. This mode of distributing time was the result of the re-(see these words).—4. The Gregorian calendar. This mode of distributing time was the result of the reform inaugurated by Gregory XIII., and dist came into operation in October, 1552. This calendar principally differed from the preceding in deducting 10 days of that year, in which it first came into operation, it having been ascertained that the error fit in minutes of the Julian year had amounted, in 1632 years, to 10 whole days. In order to prevent a resurrence of this error, it was ordered that even a recurrence of this error, it was ordered that every year ending a century should not be counted as a leap-year, excepting the 400th year, and the multiples of 400. Thus, 1200 and 1600 were leap-years, 1810 was not, nor will be 1900: 2000, as being a multiple of 400, will be a leap-year, as well as every 400th year after-wards, in addition to every fourth year when it does not end a century. The Christian peoples, while they preserved the names and the order of the months of the Romans, rejected their manner of dividing the months and counting the days; adopting, instead, the Hebrew system of dividing the mouth into weeks. The Greeks and Russians have refused to adopt the Gregorian calendar, retaining the Julian, or what is called in this country the "old style." Hence it is necessary to deduct 12 days from the new style, in order to make it agree with the old. The reason for there being at the present time a difference of 12 instead of 10 days between the old and new modes of reckoning, is due, as Assaiready been explained, to the fact that, in the Gregorisu calendar, the years 1700 and 1800 were not counted as lesp-years, while, according to the old, or Julian mode, they were so estimated.—5. The French Republican calendar. This was adopted by a decree of Republican calendar. This was adopted by a decree of the National Convention of Oct. 1793. The year was therein divided into 12 months, of 30 days each, 5 com-plementary, or "sans-culottides" days, being added at the end of each year. The commencement of the year was fixed at midnight of the 22nd of September year was used at midlight of the same of opposite the autumnal equinox), and, retrospectively, the new year, or Year L of the Republic, began on the 22nd of September, 1792. Fresh names were given to the months being, and the days; the titles of the months being, for the autumn season, Vendémiaire, Brumaire, and Frimaire; for the winter season, Nivose, Pluviôse, and Ventôse; for the spring season, Germunal, Floréal, and Tenings; and for the summer season, Messidor, Ther-midor, and Frantidor. Each month was divided into a period of three decades (10 days each), each day bearing, instead of the name of a saint, that of an agricultural product, implement, or animal useful in

cultivating the earth. This calendar remained in a during thirteen years, and was abolished by a deer

turners years, and was abunated by a comment. the emperor Napoleon L, on the lat January, 1906.

CALENDARS, in Ecol. Hist., denoted certain books preserved in the churches, containing the memorials of the days on which the martyrs suffered. Afterwards confessors, and other distinguished Christians which had not noticed at the confessors. who had not arrived at the glory of martyrdom, were also admitted to this honour. The principal work of

who had not arrived at the glory of martyrdom, were also admitted to this honour. The principal work of this kind is Assemann's "Calendar of the Universal Church," illustrated with notes.

CALENDARUM FERSTUM, kål-en'-dil-rum fer-tum (Lat., Feast of the Calends), in Eccl. Hist., were heatheuish festivals celebrated on the calends of January, and afterwards adopted by the early Christians. They were observed in the churches with masks, and were attended with a business durating and group and gross independent. with singing, dancing, and gross indecencies. Fathers and councils long laboured in vain to put down these festivals; and Tertullian, Chrysostom, and Augustine have declaimed in the very strongest terms against them.

-Ref. Du Cange, Glossarium Latinitatis-Kalendes.
CAUENDARUM FRATERS (Lat., Bretiren of the Calends), a religious society, which originated about the 12th century, and took its name from the custom of assembling together in various places on the first day of each month to regulate the observance of the ensuing feasts, distribute alms, &c. It spread over France and Germany, but afterwards, having given rise to abuses, it was abolished.

CALENDERING, kill-en-der-ing (Fr. celendrer; Gr. kulindres, a cylinder, robler), the name given to the final process adopted to finish pieces of cotton, or linen, for the operations of the calico-printer, or for sale. It is done by passing the wobs between cylindres and the contract of ders subjected to enormous pressure, and the process directly derives its name from the cylinders that are used to smooth, or flatten, the cloth that is passed between them. When clothes have been washed, they between them. When clothes have been washed, the are subjected to a simple form of calendering passing them through a mangle, or by starching, and afterwards pressing them with the common smoothingiron. The patent mangle is somewhat similar to the machines at present used by manufacturers in the general principles of its construction; and the old mangle, in which clothes were pressed on rollers that moved backwards and forwards on a level surface under a heavy box filled with stones (see MANGLE), was identical with the old calendering machines, with this difference only, that they were larger and heavier, and When the French and turned by horse-power. Dutch Protestants were obliged to quit their respective countries on account of the severities pract against them, they introduced the cylindrical calcu-dering machine, in which the cloth is passed between cylinders, instead of between rollers and a flat surface as in the mangle, by which improvement every part of the piece receives a uniform pressure, and is passed through in one direction, from end to end, instead of being rolled backwards and forwards on rollers under a heavy traversing-box. The cylinders were formerly made of wood, but they are now made of paper and east iron, or copper, a cylinder of paper working against one of iron, which is found to be better than iron working against iron, as the paper cylinders combine some slight degree of elasticity with the extraordinary hardness they possess. These cylinders are made of discs, or plates, of thick pasteboard, with a hole in the centre to receive an iron axis, and others near the circumference, through which long iron bolts, with nuts and screws at either end, are passed. Iron plates are added at the ends of this cylinder of pasteboard disks, and the whole is tightly compressed by the action of the screws. The surface of the roller is rendered true by turning it in a lathe The iron cylinders which are used in conjunction with those of paper are hollow, and heated by the intro-duction of steam, or red-hot heaters. The calendering machine consists of four or five rollers placed in a strong framework, generally of cast iron, one above another. The pressure with which these rollers work against each other is regulated by levers. If smoothing only is required, the rollers are so regulated that their surfaces may travel with uniform velocity, although they may be of different sizes (that is to say, if two rollers were in juxtaposition, one of which was size

#### Calendars

inches in diameter and the other twelve, the smaller roller must revolve twice while the other is going round once, as the circumference of the larger one is equal to extent to twice that of the smaller); but if the is equal in extent to twice that of the smaller); but if the material is required to be glased, the rollers are so set that their surfaces may travel with different velocities, in order that the surface of one may fub against the surface of that next to it. When fabrics are calendered, they are first subjected to slight pressure between warm eginders. They are then prepared with starch, which is sometimes adulterated with plaster of Paris, to give an appearance of substance to the material and again passed through the machine. The round and agan passed through the machine. The round threads of which the web is composed are then found to be flatened, and the texture of the fabric rendered to be flatened, and the texture of the fabric rendered closer, which is the main object of calendaring. When the fabre is to be glazed, as chintz, for curtains and the cowrings of chairs and solas, very hot copper rollers we used, which rub as well as press against the paper chinders to produce the desired polish. Watered goods are made to present their peculiar appearance by passing them under a metal cylinder with a raised patern on it, which produces a greater pressure on some jarts of the cloth than on others. Lawns and muslins we only subjected to a light pressure, that is just sufficent to smooth the surface without flattening

small artices, or made-up goods with seams in them. CALENDER, käll-en-ders, a Mohammedan sect, which take their same from Santon Calendri, their founder. They preacl in the market-places, and live upon what their heares are pleased to bestow; but they are distinguished hore by free living than austerities, and

the thread Glazing was formerly effected by stretching the fabricon a table, and rubbing it with a polished flint, and his method is now sometimes adopted for

are held in litle esteem.

CALENDS, or KALENDS, kall-ends (Lat. calenda), in Roman chonology denoted the first days of every month, beingso named from culo, I call or proclaim, month, beingso named one cato, I can or procum, because then the priests proclaimed the number of fasts or sacred days to be observed in the month. The Romans evided their month into three periods,—the Calends, Nuce, and Ides. The calends always fell on the 1st of te month, the nones on the 5th, and the ides on the 13th, except in the months of March, May, July, and ctoher, when the nones fell on the 7th, and the ides on he 15th. The days of the month were then reckoned bekwards; thus the 30th of April was the day before the calends of May, or the second day of the calends, to 29th the second day before the calends, and so o to the 13th, when the ides com-menced, the 12th bing the day before the ides, and the 4th the day beforthe nones. As the Greeks did not reckon their days a this way, the Romans had a proverbial expression, of Gracas calendas (on the Greek calenda), meaning ever. The calenda were usually the time for settlin accounts, interests, &c.: hence they were sometime-railed triutes calenda. The book in which an account othe interest was kept was termed

CALERDULA, kil-en/lu-la, in Bot., the Marigold, a gen. of plants helonging to the nat. ord. Compositae, sub-ord. Tubiliforae. he species C. afficinalis is the common Marigold of English gardens, the Gold-blume of the Germans, the Shei du jardin of the French, and the Furrancio of te Italians. Formerly, many medicinal virtues were veribed to this plant, and its flowers were usually add to soups to colour them. and also to act as " comfolers of the heart and spirits." Baffron is frequently adultrated with the yellow florets Saffron is frequently admirated with the yellow librets of the marigold. The nale is stated to be derived from calendulas, the Latit for the first day of the month, there being flowertalmost any month in the year.

CALENTURE, kill-en-ture Lat. cales, I make hot) is a term derived from the Spanish, and applied to a violent ardent fever common mong sailors in very hot climates. It is so called either as being accompanied by a burning heat, or as resulting from the great heat

of the climate.

CALERIN, kill-e-pan(g)', a Fiench term, denoting a sollection of literary or scientific notes or information, a pockethook in which one inscribes his observations or reflections, or a lexicon. The word is derived from Calepino, a learned exicographer of the 15th century,

# Calico-Printing

who took his name from his native place, Cal Italy, and was the author of a celebrated dictionary, which subsequently passed through editions.

CALF, GOLDEN, kalf, in Sacred Hist., was an id set up and worshipped by the Israelites at the idset up and worshipped by the Israelities at the four of Mount Sinai, in their passage through the will derness to the land of Canann. The people faccylinit, from the long tarrying of Moses on the mount, that they were deprived of his future guidance, prevailed upon Aaron to fashion them a golden calf, that they might worship as they had seen done in Egypt, and for that purpose they contributed their ear-rings. This calf Moses is said to have burnt with the, reduced to reach a reach a travel it won water and started it was read and and a feel. to powder, and strewed it upon water, and made the children of Israel drink, the object of which probably was to testify his contempt for such gods, and to show their powerless they were to save themselves from destruction.

CALIBBE, kil'-e-ber (Fr. calibre), in Mil., the technical expression for the diameter of the bore of any kind of cannon, rifle, or fowling-piece. The capacity of mortars and other guns used for throwing holity shot and shells is usually expressed by nearing their calibre, as 10-inch howitzer, 13-inch mortar, &c.; while pieces of ordnance, from which solid shot are fired, are, on the contrary, spoken of in accordance with the weight of the shot they throw, as 12-pounder, 300-pounder, &c. The compasses, with enryed legs, used for taking the diameter of shot and shells and cylindrical bodies, are called calibre compasses, or,

improperly, callipers.

Caltoo, käll-e-ko, plain cotton cloth, which sonstitutes one of the most important British textile manufactures. It derives its name from the town of Calicut, in India, whence it was first imported. (See

COTTON MANUFACTURE.)

CALICO-PRINTING, the art of impressing cotton fabrics with arious figures in one or more colours. In describing this art, the term will be taken in its widest sense, as signifying printing on any fabric, whether cotton, woollen, or silk. There are few dyes which of themselves will impart to cotton a brilliant colour, able to resist the actions of light and washing. The dye must be combined with a substance called a mordant, which has an affinity both for the dailed a morcant, which has an aminty both loss are dye and the cotton fibre. These substances, although generally colourless, have the property of changing, the colour of the dye. Thus, if a piece of cotton cloth be impressed with acetate of alumina in lines, with acetate of iron in dots, and with a mixture of the two in circles, it will become permanently impressed with red lines, black dots, and chocolate circles. The pro-cess of printing in different colours by means of morcess of printing in different colours by means of mor-dants is very ancient, being described by Pliny as having been practised in his day in Egypt. In his Natural History he says: "Robes and veils are painted in Egypt in a wonderful way, being first im-bued, not with dyes, but with dye-absorbing drugs, by which they appear to be unaltered; but when plunged into a caldron of boiling dyestuff, it is curious to see many colours imparted to the robe, in consequence of the modifying agency of the excipient drug." In India, the modern method of printing by resist pastes has been known from time immemorial, the process fabric by hand with melted wax. Many of the speci-mens of Indian calico-printing by this method are most intricate in their design, and must have taken a lifetime to execute. Calico-printing was first introduced into England at the latter end of the 17th century, and met with furious opposition from the silk-weavers of Spitalfields, in whose favour the English government passed several acts prohibiting the importation of Indian calicoes, and exacting heavy penalties from any one making or wearing printed calicoes. In 1730, fabrics of cotton weft and linen warp were allowed to be printed and worn, by paying a duty of 6d. per square yard; and is was not until 1774 that cotton cloth was allowed to be was not until 1/74 that cotton cloth was allowed to be printed, on the payment of a heavy duty, which was only removed in 1831. The processes employed in calico-printing are,—Singeing, by which the cloth is dennded of its fibrous flown, which would prevent the perfect application of the dyestuff. It is effected in two ways; either by rapidly passing the cotton cloth-over a

red-hot iron, or by passing it over a series of gas flames, which are sucked through the fabric by suction-tubes placed over them. The fabric is next bleached by being boiled in an alkaline bye of sods or lime, rinsed attempted in a weak solution of chloride of lime, rinsed attempted in a weak solution of chloride of lime, rinsed steeped in a weak solution of chloride of time, rinsed, again, steeped in dilute sulphuric acid, once more rinsed, dried, and smoothed. The cloth is now ready for printing, being brilliantly white, and capable of receiving dyes of the brightest and purest colours. Calicosa are printed in four ways.—by small wooden blocks worked by hand, by large wooden blocks worked by-a machine, by copper plates, and by copper cylinders. The first and third methods are almost obsolete; the assumits avantisated principally on the continent; and the second a practised principally on the continent; and the fourth is, par excellence, the English method. In the large blocks mentioned in the second method the patseems are generally made of sycamore, laid upon deal, and either engraved in relief, or formed by copper slips, of different shapes, being driven into the surface. The machine used in this style is called a Perrotine, from the name of its inventor, M. Perrot, of Rouen. The cloth as wound round a prismatic iron roller, and the different so would round prismatic from round; and the different coloured blocks are brought down on it successively. By this feeces, one man and three children can print thirty pieces of cloth in a day. In the English process, the pattern is impressed upon copper cylinders by hard steel rollers called dyes. These cylinders are mounted upon strong iron shafts, upon the end of which is a toothed wheel, by means of which motion is communicated to them. Several of these engraved cylinders, one for each colour, are united in one machine, forming two, three, five, and even ten-colour machines. The cotton cloth is made into a continuous web of forty or fifty pieces, and is drawn over the rollers, each one re ceiving its colour from a cylinder covered with woollen cloth, and revolving in an oblong trough of colouring matter, mordant, or resist-paste, and transferring it to the cloth. Calico-printings have reached such a state of perfection, that they will print nearly ten miles of cloth per day, with a pattern containing four or five colours. Dyestnffs are of two kinds, those which impart their colour alone, and those which require the applitheir colour alone, and those which require the application of a mordant. The former are called substantive, the latter adjective. (See Dyring.) There are, principally, five styles of calico-printing.—1. The Fast-colour, or chintz style, in which the pattern is applied in the form of a mordant, the cloth being afterwards passed through a dye-bath. The colour, of course, ellings only to the mordanted portion, the rest being washed out in an after-process. 2. The Rongeous style, in which the pattern is worked upon the cloth by the appearance of some chemical substance which discharges appearance of some chemical substance which discharges egency of some chemical substance which discharges ertions of the uniform colour in which the cloth was irst printed. 3. The Resist-paste style, when the pat-tern is printed in some substance which resists the general dye afterwards applied to it, such as indigo, or some other substantive colour. 4. Steam colours, in which a the union of the two being effected by subjecting it to the action of steam. 5. Spirit colours, in which a mixture of dye and tin spirits, or chloride of tin, is used. Patterns printed in this style are very brilliant, but extremely fugitive. In the first style, the mordant used may be either acetate of alumina, or red liquor; acetate of iron, or iron liquor; or chloride of tin, or tin spirits.

The mordant is mixed with starch or British gum, and different shades of the same colour may be obtained by diluting it more or less. The principal dyes and in this style are logwood, Brazil-wood, peach-wood, Persian berries, archel, madder, cochineal, fustic, secod. Fersian berries, archel, madder, cochineal, fustic, estecsies, quereitron, and galls. (The different colours estecsies, quereitron, and galls. (The different colours british dyestams will be found fully described under DYRING.) In the rongeant, or discharge style, the discharge generally consists of some strong acid, such as strictle, oxalie, or tartaric acid, made into a paste with pipolary and gum, and applied either to the dyed or meridanted cioth. In the latter method, a new mortant may be applied along with the discharge, in which case a coloured pattern will be the result. For fundament, a violet cround with red lines and which astance, a violet ground, with red lines and white fastance, a violet ground, with red lines and white dots, may be produced by passing the cloth through weak is on liquor, and printing the lines with red liquor mordant. The dots are then printed with a distance paste of tartaric and oralic acid, and the whole

403

is passed through a madder dye-vat. In the resist, or reserve style, various substances capable of resisting the action of substantive dyes are used; such as oil the action of substantive dyes are used; such as oils metallic oxides, and their salts; and reserves, containing mordants, are used, when a coloured impression is desired. The latter method of printing with mordant resists is called the lapis lands style, wherefore it is hard to say. Steam colours are mostly produced by the aid of peroxide of tin, of stantage acid, or perchloride of tin is used as a moriant. A full-bodied red, for instance, is produced in the following manner:—A decection of peach-wood is bickened with gum, and mixed with chloride of tin. Thi impress sion is printed on the cloth with this mixture, and, when dry, the goods are submitted to the action of dy steam, which causes the union of the substances dutained in the dyestuff. Spirit colours are brilliant put very fugitive. They are mostly vegetable dyes, mad with perchloride of tin, or tin spirits, as it is termed A sixth style—Pigment printing—is when a heavy, insoluble colour, such as ultramarine or magenta, is mxed with gutta-perchasolution, albumen, or caseine, art printed on the cloth. Since the introduction of the adine dyes, this method of printing has somewhat reved. By the combination of superexcellence in maginery and chemistry, England is now at the head of the calico-printing trade; the exports reaching, it 1857, 808 millions of yards; but it will be long before she will succeed in rivalling the exquisite printed muslins of the French manufacturer. Though taking the lead in the French manufacturer. Though taking the lead in machinery and chemistry, we are very far behind in the artistic portion of the trade; the string combinations of twenty colours of Manchester contrasting very unfavourably with the artistically lended hues the commonest productions of Milhouse and Paris.

CALIF, CALIFH, or KALIF, kai lift Arab, lieutenant or vice-gerent), the title assumed by the successors of Mohammed in the supreme ower. It was first adopted by Abu Bekr, his immedate successor, and continued for a number of centuris to be the title of the principal line of sovereigns. The term califate was employed to designate the empireunder the sway of the califs. After the death of Mohammed, his successors extended their empire so astly, that, 100 years after his flight from Mecca, the bounds of the califate extended from India to the Alantic Ocean, in-cluding Persia, Syria, Egypt, and pain. "The lan-guage and laws of the Koran were tudied with equal ction at Samarcand and Seville : the Moor and the Indian embraced as countrymen ad brothers in the pilgrimage to Meeca; and the Arbian language was adopted as the popular idiom in it the provinces to the westward of the Tigris."—(Gibon.) At this time, the calfs were the most potent ad absolute monarche of the globe. They united in hemselves both the regal and sacerdotal character; their prerogative was not circumscribed, either irright or in fact; and if the Koran was the rule of teir actions, they were the supreme judges and interreters of that divine book. The empire reached is greatest power and splendour during the latter art of the 8th and the beginning of the 9th century of our era, under the culifs Mansur, Harun-al-Rasid, and Mamun. Even then, however, the empirewas beginning to show symptoms of decay, and, eder Mamun's successor, Mostasem, Turkish soldier were employed for the first time in the army. Inder his successors, these came to be a formidable pwer in the empire, and at tength assumed the right c deciding the succession to the throne. Independently assume sprung up in different parts of the empire and even within the capital and provinces that contined faithful, the authority of and provinces that contined faithful, the authority of the calif was little more aan nominal. In 1258, "after a siege of two months, Bgdad, the capital, was stormed and sacked by the Moguland their savage commander pronounced the death of the calipla Mostsaem, the last of the temporal successors of Mohammed, whose noble kinsmen of the race of shoas had reigned in Asia shore 500 years."—Gibbon.) The nephew of the murdered Mostasem fled to Egyp, where he retained the title of calif, under the protection of the Mamelnikes, and be-quenthed the honour to dis successors. When the quenthed the honour to his auccessors. When the Turks conquered Egypt, in 1517, we last of the nominal califs was carried to Constantinple, and since that

Calign

time the Purkish sultans have assumed the title of calif, and claimed to be regarded as the spiritual head of the Moslems

Of the Robisma.

Callen, kall-o-js, is a term derived from the
Latin caliga, a kind of shoe, or rather half-boot, worn
by the Roman soldier; and hence, in the early ages of
the Church, it was applied to a similar article of dress,
which found part of the insignis of a bishop, and was
emblematical of the spiritual warfare upon which he

Calife, kal-e-go (Lat., darkness), is a term employed In Med. to denote dimness or obscurity of vision; and hence it terms part of the name of various diseases of the eye attended with dimness or loss of sight; as caligo comos, lentis, humorum, &c. (See BLINDNESS, EYE.)

CALLGRAPHY, kul-ig-ruf-e (Gr. kalos, beautiful, graphs, writing), is the art of beautiful writing. Previous to the invention of printing, this art was greatly fostered, and many admirable specimens of it still exist. Some of them are written in letters of gold, vermilion, &c., on leaves of various colours, and richly ornamental with beautiful devices. The scribes who were employed in thus copying MSS, were termed caligraphes.

CALIPPIC PERIOD, or CYCLE, kil-ip'-ik, in Chron., receives its name from an Athenian astronomer, Calippus, by shom it was first observed, about B.C. 330. About a concury before, it had been discovered by Meton, that in nineteen years there are 235 lunations, when the nev and full moons return to nearly the same day and hour Calippus observed that this would be more nearly the case by taking four Metonic evcles or periods of nileteen years, and then subtracting one day. The Cuippic period is thus 70 years, less one

CALISTHENIUS, kal-is-then'-iks (Gr. kalos, beautiful sthenes, strength), the science or practice of exercising the limbs and body for the purpose of strengthening the muscles and acquiring a more graceful carriage. (See GYMNASTICE.)

CALITRICHACEE, kul-it-ri-kai'-se-e (Gr. kalos, beautiful, fhrix, mir), in Bot., the Starwort family a nat. ord. of heotylethologus plants, in the subolass Monochlamylea. olsas Monochlumyles. The species are small squa-tic herbs, having the following general characters: Leaves opposite, entire, simple; flowers minute, axillary, solitary, wisexual, schlamydeous; the male flower of 1-2 stamens, with reniform anthers, the female flower having a 4-cornered, 4-celled overy, with one suspended vule in each cell; fruit indehis cent, 4-celled; seeds 1, pellate, with fleshy albumen; embryo inverted, with a very long superior radicle. Calitriche is the only jenus, and includes six species, natires of fresh-waterpools in Europe and North

America. Their uses at unknown.

CALIVER, kul-1-ver, a land-gun in common use about 1600, that could be discharged from the shoulder with-

1600, that could be discharged from the shoulder without a rest. It was fired b' means of a matchlock. The barrel was shorter than hat of the old musket, and much lighter, and the dispeter of its bore was made according to a fixed standed; hence the name of the weapon, corrupted from calore. (See Calibre.)

Calixines, kd'-iks-tines Lat. calix, a cup), a Bohemian sect which sprung upamong the Hussites, and received their name from holding that the communionup should be given to the lay as well as the clergy. Their confession of faith, draw up in 1421, contained the following articles:—1. The Vord of God should be freely, and without hindrance, regularly preached by the following arrange.—In the voru of troat should be freely, and without hindrance, egularly preached by the priests of the Lord, throughout Bohemin; 2. the sacrament of the holy communion the wine as well as the bread, should be freely adminitered to all Christthe breat, should be rown saturatered to an enrist-ians burdened by no mortal sins, scording to Christ's institution; 3, the clergy should be separated from secular affairs, and should conform hemselves to the life and teaching of the aposities; \ that all mortal sins, and especially such as are of a public nature, as sins, and especially such as are on whithin enture, as simony, unchastity, and the like, and a Jothers that are contrary to the law of God, should bindged of and numished by those having authority oversuch matters. They were the more moderate of the followers of John Huss, being opposed to the more extrac sect of the Taborites. They subsequently became the dominant party in Bohemia, and exercised constrable inCali

nuence over public affairs. From the beginning of 16th century, however, they gradually lost their portance, and came to share in the fate of the E testants generally in Bohemia. (See BOHEMEAN HITRER.)

CALIXITIES, were also the followers of George Calixius, a celebrated Protestant divine of the 178 century, who endeavoured to unite the Romish, Lu theran, and Calvinistic churches in the bonds of ol and mutual benevolence. He maintained that the fun damental doctrines of Christianity—by which he mean those elementary principles whence all truths flow-were preserved pure in all three communions, and were contained in the Apostles Creed; and that the tenets and opinions that had been constantly received by the ancient doctors during the first five centuries, were to be held as of equal weight and authority with the express declarations and doctrines of Boripture

Cali Yuca, ka'-le yu'-ga, a Hindu era, taken by the Brahmins as the commencement of the present age of the world, called by them the "iron age." It dates the world, called by them the "tron age." It cause from 3102 s.c., the period of the Deluge. The year 1862 is the year 4964 of the Call Yuga era; thesefore, to bring any date of the Call Yuga era to its corresponding date according to the Christian era, we must subtract 3102 from it. The year, according to this era, com-3102 from. it.

mences in April. CALEING, kawk'-ing, in Mar., a term signifying the act of forcing a quantity of oakum into the seams between the planks of a ship's decks or eides, by means of iron chisels, called calking-irons. When the cakum has been driven firmly into these seams, it is covered

with a coating of pitch or rosin, to prevent its rotting.

CALL, kawl, is a term used in Theology in a variety of significations. In a general sense, it denotes God's invitation to man to never to f the offer of salvation. Effectual calling is said to be "the work of God's Spirit, whereby, convincing us of our sin and misery, en-lightening our minds with the knowledge of Christ, and renewing our wills, he doth persuade, and enable us to embrace Jesus Christ, freely offered to us in the governel." Call to the ministry, is said to be twofold; either outward, when one is judged qualified to hold office in the church, and is admitted thereto in due form; and inward, when one is inwardly moved thereto by the Holy Spirit. This inward call should precede, and is required as a qualification for the outward. didate for deacon's orders, in the Church of England, is asked, "Do you trust that you are inwardly moved by the Holy Ghost to take upon you this office and ministration to serve God, in promoting his glory, and the edifying of his people?" According to Dr. Hook, the meaning of this question is, "whether, after an im-partial examination of their hearts, they find that they do not take this sacred employment upon them, barely for a maintenance in the world, or that thereby they for a maintenance in the world, or that thereby they may acquire those superior dignities and profits which, in these penceable ages of Christianity, some of the clerky do partake of, but only that they think they may be serviceable in God's vineyard, and are willing to contribute the best of their labours therein for the promoting of God's glory, and the edifying of his people."—(Church Dictionary.) Calvin defines the inward call, in his Institutes, to be "the good testimony of our own heart that we have taken this office, neither for whitten correleveness now any avil degires but out of ambition, covetousness, nor any evil design, but out of a true fear of God, and a desire to edify the Church." Call, among Presbyterian churches, is applied to the invitation given by a church to one duly qualified to become their pastor. The question as to the right of a congregation to choose their own pastor has led to frequent dissensions in the Church of Scotland, and was the cause of the disruption of that body, which took place in 1843. (See PATRONAGE, FEER CHURCH. SCOTLAND, CHURCH OF.)

CALL (Fin.), a term used in monetary transactions, signifying a demand for the payment of certain instal-ments due on shares issued by joint-stock companies. In the formation of such companies, shares of a fixed an une formation of such companies, shares of a fixed amount are offered to the public, purchasable upon expressed conditions. A stipulated sum is paid upon the delivery of the preliminary acknowledgment, sectionally known as scrip; and all shareholders are liable to be "called" upon from time to time to pay further sums, until this amount is paid up; hence the parass.

This application is usually regulated by the board of directors, and is dependent upon the progress of the speculation or the necessity that may exist for the employment of additional capital. It has, however, a somewhat different meaning on the Stock Erchange, somewhat different meaning on the Stock Exchange, where a "sall" is then a person gives so much for the option of baying stock (public securities) at a specified time, the price and date being settled at the time the option smore is given.—Ref. Fenn on the Funds, do. Call, a kind of silver or brass whistle, used by the

bostswain and his mates to summon the sailors to their posts, and to direct them about the various employments of the ship. A gold call was formerly the insignia of an admiral.

Casa or THE HOUSE, in parliamentary proceedings s an imperative aumons, issued to every member of seither house, to attend on some particular occasion, when important matters are to be brought before them. In the House of Lords, when any urgent business is deemed to require the attendance of the Lords it has been usual to add the backen used to the lords of the lords it has been usual to add the backen used to require the strendance of the Lords, it has been usual to order the house to be called over; and this order has sometimes been enforced by fines and imprisonment upon absent lords. The most important occasion on which the house was called over in modern times was in 1820, when the bill for the degradation of Queen Caroline was pending. The bouse then resolved "that no lord do absent himself on pain of incurring a fine of £100 for each day's absence, pending the three first days of such proceed-ings, and of £50 for each subsequent day's absence from the same; and in default of payment, of being taken into custody." When the House of Commons is ordered to be called over, it is usual to name a day which will enable the members to attend from all parts of the country. If it be really intended to enforce the call, not less than a week, or ten days, should intervene between the order and the day named for the call; the interval, however, has varied from one day to six weeks. The order for the house to be called over is always accompanied by a resolution, "that such members as shall not then attend be sent for, in custody of the sergeant-at-arms." On the day appointed for the call, the order of the day is read and proceeded with postponed, or discharged, at the pleasure of the house. If proceeded with, the names are called over from the Return Book, according to the counties, which are arranged alphabetically,—
the members for the county being called first, and
then the members for the oities or boroughs within
that county. The counties of England and Wales are called first, then those of Scotland and Ireland in their order. The names of members who do not in their order. in their order. The names of members who do not answer when called are taken down by the clerk of the house, and are afterwards called over again. If they appear in their places at this time, or in the tours of the evening, it is usual to excuse them for their previous default; but if they do not appear, and no excuse is offered for them, they are ordered to attend on a future day. It is also customary to to attend on a future day. It is also customary to excuse them if they attend on that day, or if a reasonable excuse be then offered; but if a member

called earns is they accend on case day, or is feasonable excuse be then offered; but if a member
should not attend, and no excuse is offered, he is
liable to be committed to the outsody of the sergeantst-arms, and to the payment of the fees incident to
that commitment.—Ref. May's Low of Parliament.

Call of the Same Same of Calling the Calling of Calling the Calling of Calling the C

form), small beetles, infesting houses, and very destrucform), small bestles, infesting houses, and very destruc-tive to woodwork, especially of spruce and fir. One of this family (Callidium bejulus), a flattish, rusty-black insect, will, according to Messrs. Kirby and Spence, but even hore through sheet-lead; fragments of lead having been found in their stomachs. Calling been found in their stomachs. Calling or found in their stomachs. Calling or found in their stomachs. Talling or found in their stomachs. Calling been found in their stomachs.

drangular fruit, winged at the angles. The species C. Pallasia, which is found on the sandy steppes near the Caspian Sea, is valued by the wandering Kalmucks for the acid juice of its fruit and aboots, which often serves to aliay their thirst; and also for the nutritious gum which may be obtained from its

root.

CALLIFEDIA, käl-le-pe'-di-d (Gr. kalles, beauty, paidia, children), the name of a Latin poem in four books, by the French abbot Claude Quillet de Chinon, and published under the fictitious name of Clavides Lectus. The full title of the work is "Callipedia; seu, de pulchræ Prolis habendæ Ratione;" and was translated into Euglish verse by Nicholas Rowe.

CALLIPERS. (See CALIBER COMPASSES.)
CALLIPERS, kill-e-tris, in Bot., a gen. of conference plants. C. quadrivalvis, the arar-tree, yields the resin called sandarach, juniper resin, or gum-juniper, which is imported in large quantities from Magadore. It is nuch employed in the preparation of varnishes. When powdered, it is called pounce. The timber furnished by this tree is very durable, and is used by the Turks for the floors and ceilings of their mosques.

Callosity, kil-os'-i-te (Lat. cullositus), it an indura-tion or hardness of the skin; as that of the hands

through bard labour.

CALLUS, kall-us, in Surg., is the bony natter which is deposited between the fractured ends of broken bones. It is an osseous substance, formed by a process of nature for the reuniting of brokes bones.

Calm, kum, in Mar., the name given to that atate complete rest in the air when there is no wind stirring. The regions in the immediatevicinity of the equator are the parts of the ocean where the mariner is overtaken by the most frequent and most durable culms. In the Atlantic Ocean the region of calms has a breadth of six degrees. The Pacific Ocean derives its name from being characterized by an equatorial belt of calm region averaging five degrees in breadth, and lying between the south-eastern and north-eastern trade-winds. (See TRADE-WINDS.) In these came latitudes rain is constantly falling; and when Captain Wilkes, of the United States exporing expedition, traversed them in 1838, he found that in the ten days he was making the journey the constant aqueous precipitation was at the rate of upwards of eighteen feet per year. The calm latitudes of the Atlantic Ocean are situate between the tropic of Cancer to very nearly lat. 29° N.

CALOMEL, käl-o-mel (Gr. kats, good, melas, black, from the qualities and colour of he Ethiop's mineral to which the name was original! applied), chloride of

which the name was original applied, cultival of mercury. (See Mrscurx, Chordible Or.).
Calophyllium, kalo-fill-un (Gr. kalos, beautiful, phullon, leaf), in Bot., a ger of plants belonging to the nat. ord. Guttiferæ, including many valumble timber trees. C. angustifolium, thepiney-tree of Penang and the islands to the eastward of the Bay of Beugal, furnishes fine straight spars. C. calaba and C. inophyllum, besides yielding timbe, produce seeds from which good burning oil is obtained. The fragrant resinons substance known as East ndian tacamahaca is a product of the species of this genus.

Calou Mondicans, ke'-or mor'-de-kans (Lat., biting heat), in Med., is applied to a particular kind of beat, that sometimes attend typhus and other fevers, and is considered a dangerus symptom. It is biting and pungent, rather than burning, and leaves a smarting sensation on the figers for several minutes after

touching it. CALORIC. (See BAT.)

CALORIC-ENGINY kallor-ik, an engine in which the power is derived from the expansion of air by beak. The calorie-engines a name given to a particular air-engine by Captai/Ericason, a Swedish engineer resident in America In its working parts, the caloricengine closely reembles the steam-engine; the heated air acts upon spiston which works in a cylinder, and the piston-rod ad connecting rod convey the power to the crank an main shaft. The calorio-engine seems the crank an main shaft. The caloric-engine accuse to resemble cosely the air-engines of Messra. Stirling. In the earlie air engines, such as those made by Sir. George Cay'y and others, the air was passed through a heated chuber, by which means it was raised to a temperatre of nearly 600°, and after doing its work is

## Ualorimeter

was allowed to escape. By this process, a great quantity of heat was wasted. In Stirling's air-oughes and in Priceson's caloric-engine, she chief improvement lies in the ingenious way in which the heat is economized. The chamber in the caloric-engine, through which the hot air passes, is filled with fine wire, putting, placed side by side, to the thickness of treelye to twenty inches. On leaving the cylinder, the air, after performing its work on the cylinder, is made to pass outwards through this chamber. In its passage, a quantity of its heat is abstracted by the metal network and given up again to accuracted by the metal network and given up again to the returning air, which passes inwards through the same chamber. The returning air, with a slight ac-cession of heat from the furnace, produces another effective stroke of the piston; heat, which would otherwise have been wasted, is thus retained, and a corresponding quantity of fresh heat and fuel is saved. Very few of the many ingenious varieties of air-engines have succeeded. In 1853, Captain Ericeson tried a very bold experiment with his caloric-engine. He introduced it into the Ericeson, a first-class vessel of the ordinary steam-boat pattern. The register of the ship ordinary steam boat pattern. The register of the ship was 1,903 tons, and she was furnished with paddles. Instead of one funnel, however, she had four small tubes, gaily painted in white and gold. The caloricengine consisted of two pairs of cylinders, connected in their action, but not placed side by side. Each pair was composed of two cylinders, of which the lower one was much the larger. The upper was called the "supply cylinder," the lower the "working cylinder," The diameter of the working cylinders was 169 inches, and that of the supply, 137 inches each. This enormous bore, however, 14 and 12 feet alternately, was found insufficient to perform the work required. Briesson afterwards reduced the size of the cylinders, and the stable conversed with the company to have and used highly compressed air. All the results, how-ever, were unfavourable. Caloric-engines, for per-forming lighter work, such as printing, &c., are much used in North America, and, with additional improvements, it is probable that they will be very extensively

CALORIMETER. (See Hrat.)
CALORIMETER. (See Hrat.)
CALOTROPIS, kā-lot'-ro-pis (Gr. kalos, beautiful, tropis, keel, in allusion to the keel of the flower), in Bot., a gen. of tropical plants belonging to the nat. ord. Asclepiadacea. The species C. gigantea or procera yields the medicinal bark known as Mudar bark, which has been much employed in India for the treatment of cutaneous affections, and occasionally as a substitute for ipeca-cuanha. It contains a peculiar principle, called muda-rins. The fibres of the bark are known under the names of Ak and Mudar fibres. The bark of the root of C. Hamiltonis has similar properties, and is said to yield the fibres termed Yercum.

ALOTTISTS, OF LE RÉGIMENT DE LA CALOTTE, kalog-ists, the name of a society of wits and satirists in France during the reign of Louis XIV., at the head of which were Torsac and Aimon, officers of the royal guard. They took their name from calotte, a little cap, such as was worn by the monks to cover the tonsure. If any public character committed a ludicrous or stupid blunder, the society would send him a patent to wear the calotte as a protection for the weak part of his head. The arms of the society consisted of various in-signis of folly, and it had for its motto, C'est regner signs of folly, and is had for its motion, or ear regimer que de scooir rire. As it numbered among its members many persons of high rank, it was possessed of con-siderable power, and, at length, became so audacious as to attack even royalty itself. It was dissolved by the ministra Flaury. At the time of the Netwerstop the minister Fleury. At the time of the Reformation, the term regime de la calotte was applied to priestly rule

CALOTYPE, kell-o-tipe (Gr. kalos, beautiful, tupos CALOTYPE, këll-o-tipe (Gr. kalos, beautiful, tupos, impression), a name given to a process in photography discovered by Mr. Fox-Talbot. It is often called the Talbotype, but the name at the head of this paragraph is the most usual. The method of taking calotypes is as follows:—A piece of paper is saturated with a solution of iodide of potassium, dried, and laid on a bath of nitrate of silver. Iodide of silver is formed, and the paper is washed in clean water, and dried. When examined in a good light, it is found to be of a delicate canary-yellow colour, due Indiana fill the calumet with the best tobacco, and to the formation of iodide of silver on the surface. It is present it to those with whom they have concluded sandered sensitive to the light by being laid on a solution any important business, smoking out of it themselves.

## Culumet

of nitrate of allver, to which have been added galland acetic acid. It is then dried, exposed to the in the camera, and developed with a solution of acid to which have been added a few drops of mitrate of silver. When all the details have applit is well washed, and the unsistered iodide of all dissolved out by means of a triturated solution hyposulphate of sods. The picture is once as washed, and then waxed to render it semi-train The result is a negative picture, i.e., a pict with the lights and shadows reversed. To pro with the lights and shadows reversed. To produce a positive from this, it is superposed on a piece of schaffitzed paper and exposed to the light. The light shining through the shadows, which, being reversed, are transparent, blackens the paper, whereas the lights, being opaque, stop the light from acting on the sensitive surface, and leave it white. This operation is

called printing. (See Photography.).

Calours, kil-oi'-ers (Gr. kalogers, good old men), is a general name given to the monks of the Greek church. They follow the rule of St. Rasil, whom they church. They follow the rule of St. Basil, whom they regard as their father and founder. There are three degrees among them: the novices, who are called dechur; the ordinary professed, called Microchem; and the more perfect, called Megalochem. They are likewise divided into comobites, anchorets, and reclusive. They have four Lents, the first and greatest of which, for the resurrection of our Lord, is called the grand quarantain, and lasts for eight weeks. During this Lent the religious drink no wine. All the monks are obliged to labour for the benefit of the monastery as, long as they continue in it. The most considerable long as they continue in it. The most considerable monastery of the Caloyers in Asia is that of Mount Sinai, which was founded by the emperor Justinian, and endowed with 60,000 crowns revenue. They have also numerous monasteries in Europe, the most cells-brated of which are those of Mount Athos, in Macedonia. There are also female Caloyers, or Greek nuns, who likewise follow the rule of St. Basil, but their nun-

neries are always dependent on some monastery.

Caltha, käll-tha (Gr. kalathes, a goblet), in Bot.,
a gen. of plants belonging to the nat. ord. Runnisculacka, tribe Helleborea. The species C. palustria,
commonly known as the Marsh Marigold, grows wild in marshy places, and has showy bright yellow flowers.

CALTROP, käll-trop (Sax. coltrappe), a piece of iron consisting of four sharp spikes projecting from a com-

mon centre in such a manner that three of the points will rest on the ground and the fourth stand upright in whatever way it may be thrown from the hand. Caltrops are sometimes thrown down before infantry or artillery, to check a charge of cavalry, or in a breach to impede the advance of the storming party; they are, however, far more injurious to cuvalry than infantry. Cal-

CALTEOP.

trops are sometimes called crow's-feet.

CALUMBA, kā-lum'-ba, the name given to a root ver extensively used in medicine as a stomachic and mild tonic. It takes its name from Colombo, in Ceylon, whence it was first brought. (See JATRORHIZA.)

CALUMET, OF PIPE OF PRACE, kall-u-met, is the name given by the North-American Indians to a tobacco-pipe of a particular construction. The bowl is of pipe of a particular construction. The bowl is et polished marble, and the stem is of strong reed, 25 feet long, and adorned with looks of women's bair and

# Calumny

To present it to strangers is a mark of after them. hospitality.

hospitality.

CALUMEN. (See Inest.)

CALUMEN. (See Inest.)

CALUMEN. OATH OF, in the old law of Scotland, was an each that both parties to a lawsuit might be ordained to take, by themselves or their counsel, that they believed their case to be true and good. The object was to prevent rash and unprincipled lawsuits. An Act of Sederunt (1st February, 1715) requires, that before asking the oath, a sum shall be consigned, to be forefisted to the other party on his deponing in to be forfeited to the other party on his deponing in the affirmative. Though still recognized, it is now

the afficientive. Though still recognized, it is now almost anknown in practice.

Carvary, kill-nd-re, in Roman Catholic countries, is a name given, from the mount on which Christ was crucified, to certain places either adjoining a church and the countries of the country where are represented various outside a town, where are represented various somes of the passion of our Lord. One of the most selebrated is that of Mount Valerian, near Paris, which is composed of seven chapels, in each of which some mystery of the Passion is represented.

\* CLLYMISM, kill-vin-irm, is the name given to certain theological doctrines, after John Calvin, the celebrated reformer. Generally, all who hold these doctrines, of whatever sect, are termed Calvinists; but it is applied more particularly to the reformed churches of Switzerland and Germany, as distinguished from the Lutheran. Luther, notwithstanding his dauntless courage in opposing the corruptions of the papacy, and the part thing which gave offence to a number retained many things which gave offence to a number of the reformers. He was disposed to treat with toleration images, alters, wax tapers, private confession, and the mass. To all of these Calvin was opposed. He declared the Church to be a separate and independent dens body, endowed with the power of legislation for itself, and left to the civil magistrate little more than the privilege of protecting the Church and providing for its wants. He maintained that the Church ought to be governed like the primitive Church, only by synods and presbyteries, that is, by assemblies of ciders, composed both of clergy and laity; and that among the ciergy all are by the law of Christ equal in rank and authority. His religious discipline was severe, and excommunication was a civil sentence. In divinity, Calvin was an implicit follower of St. Augustine, and taught, with the great Latin father, the doctrine of the absolute decrees. The leading doc trines of Calvinism, as opposed to Arminianism, and as explained and confirmed by the synod of Dort, are the five following :- 1. That God has chosen a certain number of the fallen race of man unto eternal glory before the foundation of the world, without the least foresight of faith, good works, or any conditions per-formed by the creature, and that the rest of mankind he was pleased to pass by and ordain to dishonour and wrath for their sins. Predestination, however, is held not to affect the agency or accountableness of oreatures, or as being to them any rule of conduct.
On the contrary, they are supposed to act as freely,
and to be as much the proper subjects of calls,
promises, and threatenings, as if no decree existed.—
2. That though the death of Christ be a most perfect escrifice and satisfaction for sins, abundantly sufficient to expisite all those of the whole world; and though on this ground the gospel is to be preached to all mankind indiscriminately, yet it was the will of God, that Christ, by the blood of the cross, should efficaciously sedeem those, and those only, who were from eternity elected to selvation, and given to him by the Father.

That all mankind are totally deprayed in consequence of the full of Adam, who, being their federal head, his sin involved the corruption of the bosterity which corruption renders them unable of themselves to do auxthing truly good, and exposes them to his rightcous displeasure, both in this world and in that which is to come.—
That all whom God has predestinated unto hie he is pleased in his appointed time effectually to call by his word and spirit out of that state of sin and death in which they are by nature, to grace and salvation by Jesus Christ.—5. That those whom God hath effectually called and sanotified by his spirit, may fall partiety, or for a time, but shall sever fall inally, from a configuration of grace. These tenets, however, are not beld to same extent by all who bear the name of Calvinists. Ana

# Calydiflore

There are some who consider that they go too far, and these are known as Modersta Calvinists; and there are others, known as High Calvinists, who think that they do not go far enough. Calvinism originally existed in its greatest purity in the city of General whence it extended into Germany, France, the United Provinces, and Britain. In Germany the followers of Calvin constitute the Reformed Church. In Example Calvin constitute the Reformed Church. In France, Calvinism was abolished by the revocation of the edict of Nantes. In Holland it still continues to be the prevailing religion. In England it was adopted and made the public rule of faith in the reign of Edward VI.; but since the time of Elizabeth it has been on the but since the time of Elizabeth it has been on the decline, though latterly a revival has been taking place. In Scotland, Calviniam, as cetablished by John Knox, the disciple of Calvin, has been most enduring, and exists there in its greatest purity. Generally, however, the extreme doctrines of Calvin may be said to be rapidly losing ground, though Calviniam, in its milder form, is the professed creed of Presbyterians, Independents, Baptists, Methodists, &c., in both the Old and the New world.

Calx. (See Calcium)

CALX. (See CALCIUM.)

CALY. (See CALCIUM.)
CALYCANTRICEE, kill-o-kin-thai'-sc-e, in Bot., the Calycanthus fam., a nat. ord. of dicotyledonous plants in the sub-class Calyo/floræ. These are shrubby plants, greatly resembling the Rosaceæ, but they differ in having opposite leaves, which are always simple, entire, and exstipulate; sepals and petals numerous and similar in appearance; stamena with anthers adnate and turned outwards; and lastly in having convolute cotyledons. There are but two genera, Calycanthus and Chimonanthus, the species of which are natives of Japan and North America. The flowers have a peculiar aromatic fragrance. The bark of C. have a peculiar aromatic fragrance. The bark of C. floridus, the Carolina allspice, is sometimes used in the United States as a substitute for cinnamon-bark.

CALYCEBACEE, hile-es-rail-se-e, in Bot., the Calycera lam, a nat. ord. of dicotyledonous plants in the sub-class Corollifore. They are exclusively natives of South America, and hold an intermediate position between Dipsacea and Composite; being distinguished from the former by their alternate leaves, by the absence of involucels to the individual florets of the capitula, by the valvate restivation of the corolla, and by their monadelphous filaments and partially-united authers; from the Composita, by the authers being only partially united, and by the pendulous albuminous seed, with superior radicle. The properties and

uses of these herbs are unknown.

CALYCIFLORE, kales see flor'e, in Bot., a sub-class of Dicotyledones, comprising plants with flowers having the following general characters:—Calyx and corolla usually present, the petals of the latter being generally distinct, but sometimes connate (slightly connected); stamens perigynous (borne on the calyx, but free from stances perigynous (borne on the calyx, but free from the ovary), or else epigynous (apparently ecated on the ovary). The Culyciflora are subdivided into Peri-gyna and Epigyna. In the first of these subdivisions, the calyx is free, or nearly so; the stamens are usually perigynous, and the ovary is superior. In the second, the calyx is more or less adherent, and the ovary in-ferior. Professor Bentley describes fifty-one calysi-foral orders, namely floral orders; namely,— Sub-din. 1, Perigynæ.—Celastraceæ (the Spindle-tree

ord.), Stackhousiacem, Staphyleacem (the Bladder-nut ord.), Vochysiacem, Rhamnacem (the Buckthorn ord.), Anscardincese (the Cashew-nut ord.), Sabiacese, Connaraceæ, Amyridaceæ (the Myrrh and Frankincense ord.), Leguminosæ (the Bean ord.), Moringacese, Roord.), Leguminose (the Bean ord.), Moringaces, Mosaces (the Bose ord.), Calycanthaces, Lythraces, Saxifragaces, Hydrangeaces, Hensloviaces, Cunoniaces, Crassulaces (the Houseleck or Stone-crop ord.), Francoaces, Parouychinose, Portulacaces, Mesembryaces (the Ice-plant ord.), Passifloraces (the Passion-flower ord.), Malusnerbiaces, Turneraces, Parameter, Paramet

payacese, Pangiacesa.

payaces, l'anguaces.

Sab-div 2, Epigyna.—Cacurbitaces (the Gourd or Cucumber ord.), Loasaces, Homaliaces, Cactaces (the Cactas ord.), Grossulariaces (the Gooseberry or Currant ord.), Escalloniaces, Philadelphaces (the Syringa ord.), Myrtaces (the Myrtle ord.), Lecythidaces (the Brazil-nut ord.), Chammelauciaces, Barring-toniaces, Belvisiaces, Melastemaces, Opagraces (the Evening-primross ord.), Haloragaces (the Mars's-

# Calymene

tail ord.), Combretaces (the Myrobalan ord.), Rhisophoraces (the Mangrove ord.), Alangiaces, Cornaces,
Hamamelidaces (the Witch-hasel ord.), Bruniaces,
Umbellifere, Arailsone (the Ly ord.).
CALTHERS, kill-e-mel-ns (Gr. kekalumens, concealed),
in Gool, a gen. of trilobites, so named from the obscurity which long hung over the real nature of these
fossil crustaceans. The genus belongs to the Silurian
system, and is particularly well represented in the
Ladlow rocks. It is distinguished by its ovate, convex, and deeply-trilobed shell or crust, which is occasionally found coiled up like the oniscus, or woodsionally found coiled up like the oniscus, or wood-louse. The most abundant species is C. Blumenbachii, which has long been known as the Dudley locust. (See

TRILOBITE.)

DANK, kei'-like (Gr.), in Bot., the external enve-pe of the flower. It is composed of modified leaves, CALTX, key-ties (UT.), in posed of modified leaves, called sepals, which are usually green. Within the whorl of sepals there is generally another whorl of leaves, called the corolla (which see), but sometimes the calyx is the only envelope of the parts of fructification. The calyx may either consist of a number of as in the poppy, buttercup, and wallseparate sepals, as in the poppy, buttercup, and wall-flower, or these parts may be more or less united, as in the fachesia, melon, and tobacco. In the former case, the only is termed polysepalous or polyphyllous; case, the calyx is termed polysepalous or polyphyllous; in the latter, monosepalous or monophyllous, or, more correctly, gumosepalous or genophyllous. Sepals are generally of a more or less oval, clliptical, or oblong form, with the extremity either blunt or acute. In their direction they are erect, or pointed upwards; countient, or turned inwards; divergent or patulous, apreading outwards; or if their spices are turned downwards, reflexed. When of the sual green colour, the state of the colour of the sual green colour, the content of the colour of the sual green colour, the content of the colour of the sual green colour, the content of the colour of t downwards, reflexed. When of the usual green colour, they are said to be foliaceous or herbaceous; but when coloured, as in the fuchsia and tropwolum, petaloid. Whatever be its colour, the external envelope must be considered as the calyx. In describing a polysopalous uslyx, the number of parts is indicated by the prefix of a Greek numeral; thus a trisepulous calyx has three sepals, a pentusepulous calyx, five; and so on. When the sepals are of equal size and like form, and arranged in a symmetrical manner, the calyx is said to be regular; when they are of different sizes and forms, it is irregular. In a monosepulous or gamosepalous calyx, the parts adhere in various ways. Thus the union may only take place near the base, as in the pimpernel, when the calve is said to be partite; or it may extend to about the middle, as in the centaury, when it is deft or feaured; or the joining may leave but a small portion of each sepal free, as in the lychnis, so as to form a toothed calvx; or the union may be complete, as in the chrysanthemum, in which case the calvx is termed entire. The number of partitions, fissures, or teeth, is also indicated by Latin numerals, as in the terms quinque-partite (five-parted), quinque-fid (five-eleft), and quinque-dentate (five-toothed). In a monosepalous calvx the part formed by the union of the sepals is sometimes called the tube, the free portion the limb, and the orifice of the tube the throat. The tube of the calyx sometimes tude the throat. The tube of the caryx sometimes adheres, more or less, to the ovary, as in their is, gooseberry, currant, and in all plants of the Composite When such adhesion takes place, the calyx is said to be adherent or superior, because it appears to arise from the summit of the ovary. When there is arise from the summit of the ovary. When there is no such adhesion, the ovary being quite distinct, as no such adhesion, the ovary being quite distinct, as in the wallflower and buttercup, the calyx is described as free, non-adherent, or inferior. Many other terms which are sometimes applied to the calyx are explained under the heads Luar, Corolla, and Flowers.

Can, take, in Machinery, a plate with curved sides, fixed on a revolving shaft for converting a rotatory motion into a rectilinear. For instance, in the confinence with hummar a cam is fixed on a shaft and

ordinary tilt-hammer a cam is fixed on a shaft, and as it revolves, depresses the end of a lever, upon the other end of which is fixed the hammer-head.

are also called tappets and wipers.

CAMALDOLITUS, ki-mill-do-lites, the name of a religious order established by St. Romusld, a Benedictine monk, in the vale of Camaldoli, near Arezzo, in the Apennises, in 1018, and afterwards confirmed by Alexander II. in 1072. They were originally her-mits, living in separate cells; but as their wealth facreased, they came to secociate together in convents.

# Cambrian Books

They rapidly spread, and from Italy they extends into France, Germany, and Poland. They wear winto garment, and observe the sustere rules of the Benedictines; but as an order they are now almost extinct.

CAMER NUTMER, ka-ma'ra, a false or wild sus-meg, obtained from the Acrodickidium Camara, a plant of the Laurel ord., growing in Guiana. It is also known as the Ackawa nutmeg by the natives, who can-

ploy it as a spice.

CAMARILLA, kčm-d-ril-la (Sp., a little chamber, din
of camara, a chamber), is a word borrowed from Spein and employed in modern political language to signify the influence of secret and unaccredited councillors in matters of state or government. In Spain, where the term was first used, this influence has had a most permicious effect. Under Ferdinand VII. the name was applied to those flatterers by whom that monarch was mostly influenced, and who were generally men without talent, and opposed to every kind of reform. The word was also much used in France during the reign of Charles X.

Camassia, ki-misi-se-a (from quamash, its native name), in Bot., a gen. of plants belonging to the nat. ord. Liliacea. The species C. seculents, a native of North America, has edible roots, which are used by the Red Indians under the name of quamash. They are also

known as biscuit-roots.

CAMAYRU, kim'-a-yu.—A painting executed in different shades of one colour is said to be en camayeu. This term may be applied to drawings in sepis and Indian ink, and even to those in chalk and pencil. It is synonymous with the expression "monochrome;" but it was also originally applied to paintings in which more than one colour appeared, although one particular tint prevailed, and almost concealed the others.

CAMBER, kam'-ber, a term used in Carpentry to denote the convexity in the middle of a beam to prevent its becoming bent by its own weight, or the weight it has to sustain. Camber slip is a piece of wood curved differently on each side, for drawing the upper and under lines of straight brick arches.

CAMBIO, kim'-be-o (Lat., I clinnge), is a term some-times used in the mercantile phraseology of various countries, particularly of Holland, in the sense of exchange.

change.

Cambista, kām'-bist (Ital, cambista, a banker, money-changer), is a term applied to one who exchanges foreign money, or deals in foreign notes or bills of exchange. It is also applied to a book in which the weights, measures, and moneys of different countries are constant. verted into those of one particular place; as, Kelly's Universal Cambiat.

CAMBIUM, kam'-be-um (Lat. cambio, I change), in Bot. a layer of vitally active cells placed on the outside of each annual zone of wood in an exogenous stem. It is from this that the new layers of wood and liber are formed. The cells of which it is composed are of a very delicate nature, each consisting of a thin wall of cellulose, within which are situate a primordial utricle, a nucleus, and abundance of protoplasm. (See CELL.) a thin wall of The cambium layer is dormant during the winter, at which time the bark is firmly attached to the wood beneath; but in spring it is in full scrivity, being charged with the elaborated sap of the plant; and then the back may be separated from the wood beneath. At all seasons, however, the bark and the word are organically connected, and can only be separated by rupturing the delicate cells of the cambium-layer.

CAMBOGE, improperly GAMBOGE, kam-bogi, a gum resin exuded by one or more species of Garvinia, trees found principally in Siam. It is soluble in elcohol, and found principally in Siam. It is soluble in alcohol, and forms an emulsion with water. It is much used as a pigment, and also occasionally in medicine. It acts, when swallowed, as a powerful drastic purpative. A specimen of Siam camboge, analyzed by Dr. Christison, contained 74 per cent. of resin and 22 per cent. of arabin, the rest being moisture. Its use as a medicine must be carefully regulated, as the slightest overdose causes violent purgation and vomiting. It is said to form a considerable portion of a certain quack medicine sold by a self-constituted "College."

CAMPATAN ROCES, kms. bre-can, in Occl., a term spelied by Professor Sedgwick to the lowest focularous rocks, on account of their extensive develop-

ment in North Wales, anciently called Cambria. According to the classification of the government geological surveyors, the term is at present limited to a series of anadstones, gristones, and slates, which undorlie the Bilurian Lingular strata. (See SILURIAN

CARRIAGO Locim'-brile, a fine linen fabric, first made at Cambray; hence its name. It bears the same relation to linen that muslin does to calico. Scotton cambric is made of hard-twisted cotton. The French material batiste, so much used for printing, is a cotton

CAMBRIDGE MANUSCRIPT. (See BEZE CODEX.) CAMERINGS, UNIVERSITY OF, kaim' brij, one of the wo bighest educational institutions of England, is strated in the town of Cambridge, from which it takes its hame. Its early history is involved in much obscurity, but it seems to have originated in certain schools established here about the 7th century. Ed-ward the Elder, son of Alfred, is said to have erected, at his own expense, halls for the students and chairs and seats for the doctors, at the same time appointing teachers and adopting other necessary measures for the success of the institution. Some, however, main-tain that a regular system of education was not intro-duced till 1109, when Joffrid, about of Croyland, having sent some learned monks, well versed in philosophy and the other sciences, to his manor of Cottenham, near Cambridge, they went daily into that town, mear Cambridge, they went daily into that town, where, in a hired burn, they gave lectures in the sciences, which were attended by a large concourse of students. The earliest charter known to have been granted to the university is that of 15 Henry III. (1229). At this time, the students lodged in the houses (1229). At this time, the students lodged in the houses of the citizens, and the extravagant demands for rent gave rise to numerous disputes between the scholars nd townsmen; and hence the king ordained that townsmen; and nence the king ordanised that fazors be appointed, namely, two masters and two respectable and lawful men of the town, to fix the rent to be paid by the students for lodgings at a reasonable rate. Afterwards, hostels or hulls began to be established, where the students lived at their own charges, under the superintendence of principals, who their pupils. The first endowed college was that of St. Peter, founded in 1257; and, as the colleges began to increase, the hostels disappeared. Of the other colleges, five were incorporated during the 14th century, four in the 15th, six in the 16th, and one, Downing College, in 1800. All of these colleges are maintained by the endowments of their several founders and benefactors. The university obtained its first formal charter of privileges from Edward I. in 1291, and subsequent charters, with various privileges, were granted by Edward II., Edward III., Richard II., and Henry IV. Additional privileges were conferred upon they Henry V.,
Edward IV., Henry VII., Henry VIII., and Queen
Elizabeth, in the third year of her reign. By act of
parliament, 13 Eliz. c. 29 (1570), all preceding grants,
from Henry III. downwards, were confirmed, and the
university was declared to be incorporated by the name university was declared to be incorporated by the name of "the chancellor, masters, and scholars of the University of Cambridge." In 1614, James I. conferred upon it the right of sending two members to the House of Commons. The present university statutes were confirmed by Queen Victoria, by order in council, Mat July, 1858. The university "is a union of seven-seem colleges or societies, devoted to the study of learning and knowledge, and for the better service of the cohurch and state." Each college is a body corporate hourd by its own statutes, but is likewise constants. the church and state. Each conege is a may con-perate, bound by its own statutes, but is likewise con-trolled by the paramount laws of the university. Each of the seventeen colleges or departments in this literary republic furnishes members both for the executive and legislative branch of its government. All persons who are masters of arts or law, or doctors in one or other of the three faculties, viz. divinity, law, and physic, having their names upon the university register, have es in this assembly or senate. Their meetings are heid in the senate-house. The council of the senate established by 19 & 20 Vict. c. 88, consists of the chanestablished by the 20 vice. C. co. consists of the characteristic four heads of colleges, four professors of the university, and eight other members of the senate, chosen from the electoral roll published by the yose chancellor. Two of the heads of colleges,

two of the professors, and four other members of the senate, are elected by the persons whose names are on the electoral roll, and they all hold office for four years. All public business must be approved of by the council All pools ousness must be approved to by the constant before it can be brought before the senste. A few days before the beginning of each term, the vice-chancellor publishes a list of the several days on which a congregation or assembly of the senate will be held for transacting university business. These fixed days occur about acting university business. These tixed any sociar about once a fortnight; but, in case of smergency, the vice-chancellor may summon a congregation for the dirpatch of extraordinary business, three days notice of such meeting being previously given. The principal officers intrusted with the executive are the chancellor, high steward, vice-chancellor, commissary, and assessor. The chancellor is the head of the whole university, and presides over all cases relating to that bedy. In him is vested the sole executive authority within the precincts, except in matters of mayhem and felony. The office is tenable for two years, or for such longer period as the tacit consent of the university may choose to allow. The high steward has special power to take the trial of scholars impeached of felong within the limits of the university, and to hold and keep a list according to the established charter and custom. The vier-characterior is elected annually on the 4th November Ly the senate, and his office em-braces, in the absence of the chancellor, the execution oraces, in the absence of the chancellor, the execution of his powers, and the government of the university, according to her statutes. The consistancy is an officer under the chancellor, and appointed by him, who holds a court of record for all privileged persons and scholars under the degree of M.A. The assessor is an officer specially appointed to assist the vice-chancellor in his court. The sex wiri hold office for the court and their housings is the hear and a statute for the court. two years, and their business is to hear and adjudicate, together with the vice-chancellor, all accusations against members not in statu pupillari for offences against the statutes or ordinances of the university. They may statutes or ordinances of the university. They may punish by deprivation or suspension of degrees, but there is liberty of appeal from their decision to the senate. The public orator is the voice of the senate upon all public occasions. The two proctors, who must be masters of art or law of at least three years' standing, or bachelors of divinity, are elected annually, and their especial duty is to attend to the discipline and behaviour of all persons in statu pupillari, and to search houses of ill fame. The registrary sees to the due form of the "graces," and registers them in the university records. The two moderators superthe university records. The two moderators super-intend the examinations of the candidates for honours in the mathematical tripos. Two pro-proctors are appointed to aid the proctors. The three eaguire bedsite tend the vice-cusncellor, whom they precede with their silver maces upon all public occasions and solemnities, and summon to the chancellor's court all members of the senate. The two members of parliament are chosen by the collective body of the senate. The professors are paid some from the university chest, others by her Majesty's government, or from estates left for that purpose. The annual income of the university is derived from various sources, the principal of which are the following :-- the rectory of Burwell and a farm at Barton, producing about £1,000 per annum; the fees at matriculation and for degrees, and the profits of the university press, in all probably amounting to between £5,000 and £8,000. The funds are managed by the vice-chancellor, or by specific trustees, and the accounts are examined annually by three auditors, appointed by the senate. The terms of the university are three,—Michaelmas, or October term, from the lat October to the 18th December; Lent, or January term, from the 13th January to the Friday before Palm Sunday; and the Easter, or Midsummer term, from the Friday after Easter-day Midsummer term, from the Friday after Easter-day, to the Friday after Commencement-day, which is always the last Tuesday but one of June. There are four classes of students:—1. Noblemes and fellow commoners, who are generally the younger sons of the nobility, or young men of fortune; and are so called from having the privilege of dining at the fellows table.—2. Scholars, who are generally foundations members of their respective colleges, elected by direct examination, or otherwise, from the most promising and distinguished of the students, and who engage

various advantages; as having their rooms and commons free, or other allowances.—3. Pensioners, who form the great body of the students, paying for their rooms and commons, and in general enjoying to pecuniary advantages.—4. Sizzer, who are generally students of limited means, and sho usually have their commons free, and receive various emoluments, and are a longer required to perform the means. and are no longer required to perform the menial offices that they once were. A student is admitted on the boards of a college, either by a personal examinathe boards of a college, either by a personal examina-tion, or through a recommendatory certificate signed by a master of arts of the university. If the certifi-cate be deemed satisfactory, the name is at once entered on the college boards, and the student usually comes into residence at the October term following, when the academical year begins. During the first year of his course the undergraduate is a freshman; during the second a junior soph; and during the third a sentor soph. The first university examination, tech-nically termed the "previous," or "little go," takes place in the Lent term of the second year of the student's course, and a certificate of having passed this student's course, and a certificate of having passed this examination is indispensable to taking a degree. The subjects of examination are one of the four Gospels in the original Greek, Paley's "Evidences of Christianity," one of the Greek and one of the Latin classics, the Elements of Euclid, books i. ii. iii, and arithmetic, After the examination, the students are arranged in two classes,—those who have passed with credit and those who have simply passed. Rejected candidates must attend the next year's examination. Additional subjects of examination in mathematics are prescribed for those students who intend to be candidates for honours in mathematics, classics, or the natural or moral sciences; and no student is admitted to examination as a candidate for such honours who has not satisfactorily passed this additional examination. Every student must have completed nine terms' residence during two-thirds of each term, before he can take his B.A. The examination for B.A. is termed the "great go." and the candidates are called questionists. The examination of questionists who are not candidates for honours embraces the following subjects:—the Acts of the Apostles in the original Greek, one of the Greek and one of the Latin classics, history of the English Reformation, the first four and part of the sixth book of Euclid, together with such parts of alge-brs, mechanics, and hydrostatics as are prescribed by the schedule. The examination of candidates for mathe schedule. The examination of candidates for mathematical hopours, technically termed the "mathematical tripos," is confined to pure and mixed mathematics. It commences every year on the Tuesday after the 30th of December, or at the end of the tenth term. At the close of the examination the names of those who have most distinguished themselves are classed in three divisions; viz., wranglers, senior optimes, and junior optimes, which constitute the tripos, or three orders of honour. The highest of all is the senior wrangler for the year. "the greatest of English academical honours." The examination of those students who contend for honours in the classical tripos com-mences on the fourth Monday after the last Saturday of January in each year. The exumination consists of translations from English into Greek and Latin prose and verse; translations from the best Greek and Latin authors into English, and questions Greek and Latin authors into Engine, and pass this on ancient history. The names of those who pass this examination with credit are arranged in a tripos, and freet account, and third class. Two new triposes have recently been established for the moral and the natural sciences. The subjects for examination in the former of these, are moral and mental philosophy and logic, or history and political mental piniosophy and toge, or matory and political philosophy, political economy and jurisprudence; the subjects for examination in the latter, are chemistry, botany, geology, mineralogy, and zoology, with comparative automy and physiology. No student is to be admitted to these examinations (excepting candidates for degrees jure natalium) who has not passed the examination in the additional mathematical subpass with credit the examination; "and all who pass with credit the examination for either of these triposes are entitled to admission to the degree of B.A. A. B.A. may be admitted ad incipiendum in criticus at any time after three years from the comple-

tion of his bachelor's degree; the inceptors of as year becoming complete M.A. by creation on a "commencement-day." By the university statis-degrees may be conforred without residence or examdegrees may be conformed without repared that in stions on persons of certain rank or dignifications on persons of certain rank or dignifications of the certain rank of dignifications of the certain the admitted to the degree of B.D. for a degree the requisite exercises are one "sot" degree the requisite exercises are one and an English sermon. A D.D. must be a B.D. of years' standing, the exercises being one "act" and English sermon. The candidate for the degree of Las. is required to have kept nine terms at least, and to have passed the previous examination. The subj of examination are portions of the Roman civil law, the constitutional and general law of England, inter national law, and general jurisprudence. The names of those students who pass this examination with credit are arranged in three classes of honour. An L.B. may take the degree of M.L. by incepting, as in arts, at any time after the completion of three years from his in anguration. An L.M. of five years standing may presuggration. An l. M. of the years standing may pro-ceed to the degree of LI, D. after keeping an act. A student, before he can become an M.B., must have resided nine terms, and have passed the previous ex-sumination. Five years of medical study are required of candidates for this degree, except in the case of students who have graduated as B.A., when four years is deemed sufficient. There are two examinations, the first of which may be passed by the student after t first of which may be passed by the student after three years of medical study; the second, on the completion of his course. The subjects of the first examination are chemistry, botany, comparative and human anatomy and physiology, materia medica, and pharmacy and pathology; of the second examination, pathology and the practice of physic, clinical medicine, medical jurisprudence, and the medical treatment of surgical and obstetrica! diseases. All persons proceeding to the degree of M.D. are required to produce certificates of having been engaged in medical study during five years. The university also confers degrees of backletor and doctor of music, the conditions for either of which years. The inversity also contain degrees of which are the same; namely, that the candidate be a member of some college, and that he satisfy the professor of music as to his proficiency in the art, more especially by composing a solemn piece of music, to be performed at the appointment of the vice-chancellor, before the at the appointment of the vice-chancellor, before the university. Besides the honour of occupying a high place on the tripos list, the university-holds out to the ambitious student stimulants to exertiou, in the prizes which are annually submitted for competition. The principal of these are the Smith prizes, the chancellor's medals, and the university scholarships. The number of fellowships is 430, varying in value from £100 to £300; while some of the senior fellowships are of the value of £500 or more. For further information on matters connected with the university, we must refer to the Cambridge University Culeudar. The following is a list of the colleges, with the data. The following is a list of the colleges, with the date of their foundation, and number of members in 1870. A particular notice of each college will be found under ambabatical head :-

Oxumi, kam'-el (Lat. camelus) .- Of this gen. of mamraiferous ruminants there are two species, -1. the sommion camel (Camelus bactrianus); 2. the Arabian common camed (Cametus bactrianus); 2. the Arabian camed or Dromedary (Cametus Dromedarius). The first is principally distinguished by its humps being two in number, whilst the dromedary has but a single bump. The latter species is distributed over an immense extent of country, being found in Arabia, Persia, Southern Tartary, Rgypt, India, and the Canary Lalands. The common camed is not nearly so abundant, said its accorranged range much more limited. It and its geographical range much more limited. It is principally found north of the Taurus and the Himslays Mountains. The structure of the came is beautifully adapted to its various uses, and presents one of the most splendid pieces of nature's mechanism. Its percoral appearance is anything but fascinating, and, certainly, it would be more attractive on the score of cerriosity than admiration. Practically, however, the camel affords a good illustration of the truth of a cartain old proverb, implying that good looks are not always a proof of utility. The camel is distinguished from all other ruminants, except the liama, by having incisor teeth. The upper jaw contains sixteen teeth,two incisors, two canines, and twelve molars; the lower jaw, six incisors, two canines, and ten molars—eighteen The upper lip is swollen and divided, the nostrils sitt obliquely, the neck elongated, the head long, the eyes very prominent, and the ears somewhat small. The legs of the camel are long, weak-looking members, terminating with two hoofs or toes, padded with soft cushions underneath, which enable the animal to walk securely on the soft sands of the desert. The stomach of the camel is a curious construction, and enables the "Ship of the desert" to carry a supply of water wherewith it may refresh itself on its terribly long and tiresome journeys over immense tracts of parched and sandy desert, where, for days and weeks sometimes, not a drop of water is attainable. The hump is com-posed of gelatinous fat, which, by re-absorption, terniahes the animal with sustenance when the nature of the country, or any other unfortunate contingency, deprives it of a supply of food. Stored thus by the wise arrangement of Providence, with water and food, the animal may traverse in safety the most unproductive and arid country. So well is the nature of the tive and arid country. So well is the nature of the hump understood in the East, that the condition of the animal is judged of, and its improvement after a long journey measured by it. It is not uncommon to song journey measured by it. It is not uncommon to see camels come in after long and painful journeys with almost straight backs, the hump having almost entirely disappeared. The services of the camel to the wandering tribes of Arabs, and other inhabitants of the East, cannot be too highly appreciated, or, indeed, understood, by the people of civilized nations. The usual load of a caravan-camel is about five hundred-walcht. but, on extremely considered. reight; but, on extraordinary occasions, a strong and will carry a thousand pounds! It will travel that or nine miles an hour. The usual travelling eight or nine miles an hour. The usual traveling speed of a caravan is eighteen miles a day. The only part of Europe in which this animal is found is at Ples, in Tuscany. # Camellia

four or five thousand years ago. At what remets period the camel roamed at large, wild and free, is uncertain. The earliest writers make source mention of "wild camels;" and when they do so, it is not at all unlikely that allusion is made to animals which, on some occasion, have encaped from bondage, or been at free. The names of the camel in different countries. are all very similar. The Hebrew name is Gamai; it is the Djemal of the Arabs; Camelo of the Italians;

is the Djemai of the Arms; Camero of the Ribbans; in France, Chameau; in Germany, Kamel.

CAMEL (Fr. chameau), in Mar., a machine, chiefly used in Holland and Russia, for raising and carrying ships over any bars or banks that may obstruct the passage of a river. It was invented by Bakker, a burgomaster of Amsterdam, in the year 1688 or 1699. A came! is composed of two parts, the outsides of which are perpendicular, and the insides concave, shaped so as to embrace the hull of a ship on both sides. Each part has a small cabin, with sixteen snaped so as to embrace the fail of a simple ducies sides. Each part has a small cabin, with sixteen pumps, ten plugs, and twenty men. They have on deck also a large number of horizontal windlasses, from which ropes are fastened round the ship's hull. When they are used, the plugs are opened, and the water admitted until the camel sinks with the ship; all the ropes are then made loose, and the vessel is allowed to float between the two sides of the machine; on the ropes being tightened and the water pumped out, the camel rises, lifting the ship with it: both are then towed over the bar. This machine can raise a then towed over the bar. This machine can raise a ship eleven feet, or, in other words, make her draw eleven feet less water. Beckmann, in his "History of Inventions," states that the Dutch first contrived to carry their numerous fleet over the sands of the Zuyder Zee by means of large empty chests fastened to the bottom of each ship; and that this contrivance gave rise to the invention of the camel.

CAMBL'S HAIR is an article of commerce in the East, where it is much used for other purposes than those to which in other countries it is applied. The rough fabrics of the middle ages, called camelinum and camelitum, were woven of this material; and, during our own time, the Arabs make of it stuffs for carpets, tents, and wearing apparel. The Persians also apply it to similar purposes. The French manufacture hats from it. The fine hair from which artists' pencils are made is imported from Smyrna, Alexandria, and Constantinople, but it really comes from Persia. It is of three qualities—black, red, and grey, of which the best is the black. The grey is worth only half as

much as the red.

CAMELINA, kā-me-li-nā, in Bot., the Gold-of-plessure, a get. of cruciferous plants. C. fatida is sometimes found growing in fields of corn and flax in Britain. C. sativa, which is a common field-plant in France, has seeds containing much fixed oil.

CAMELLIA, ku-mel'-li-u (in honour of George Joseph Camellus, a traveller in Asia), in Bot., a gen. of plants belonging to the nat. ord. Terustramiaceae, natives of China, Japan, and the north of India, and extensively cultivated as greenhouse-shrubs throughout Europe and the States of America. The species C. japonica, which, as its name indicates, is a native of Japan, has received great attention from the florists of that country and of China from time immemorial. It has shining leaves, ovate elliptical, almost acuminate, and serrate; flowers without stalks, generally solitary, large, and rose-like. In its wild state the flowers are red; and the red single camellia is much prized by gardeners as a stock on which to graft the fine double varieties which have been developed by cultivation. Some of these varieties are of Chinese or Japanese origin; others have been raised in Britain, continental Europe, and America. Their colours are various, and the varieties differ much in the form and position

CARTLINGER. (See TREUSTREHIAGER.)

CARTLINGER. (See TREUSTREHIAGER.)

CARTLINGER. (See TREUSTREHIAGER.)

CARTLINGER. (See The Unit of the Land County, See The County, The County in the Last century, not only little known in this country, but its very existence was doubted; and somarvel, when wis ettraordinary proportions are considered. "Who can wonder at the incredibility of the people? 'I have seen an animal,' said the traveller, with the skin of a leopard, the head of a deer, a neck pliant and graceful is the swan's, so tall that three tall men, mounted on each other's shoulders, could no more than touch its each other's shoulders, could no more than touch its each other's shoulders, could no more than touch its forchead, and yet so gentle and timid withal, that the merest cur barking at its heels would put it to its utmost speed, which exceeds that of the hare or greyhound."—
(Wild Sports of the World.) These, moreover, are not all the wonders connected with the animal in question. What the elephant's proboscis is to it, as regards a grasper and a feeler, so is the camelopard's tongue to it, Its oblique and narrow nostrils are protected by a curious fringe of bristles, which it can at pleasure draw together, to the exclusion of the fine sand that the sufficating storms of the desert raise in clouds. Its full and lustrous syes are so wonderfully appointed, that, without moving its head, it can see behind, before, above; and thus defy the stealthy approach of its enemies. The legs of the camelopard have a curious, not to say awkward appearance. first impression one receives on regarding them, is that the hind ones are shorter than the fore. This is, however, illusory, and probably arises from the fact of the animal's neck stretching in a line with its back. In running, the hind legs are lifted alternately with the fore, and are carried outside and far beyond them, while the long tail, tufted at the end like that of the buffalo, is curled above the back, and swings pendulum-fashion exactly as the neck moves. From forehead to forehoof the full-grown buck measures eighteen feet, while the female, which is more slender than the male, measures about three feet less in height. Hundescribe the flesh of the camelopard as being slightly scented with the perfume of the mokanla and other flowering shrubs on which it feeds. Gordon Cumming, however, makes mention of a still more extraordinary circumstance,-that the living body of the animal emits a delicious perfume. "No pen, or words, convey to a sportsman what it is to ride into the midst of a troop of giraffes. They emit a powerful perfume, which, in the chase, comes hot on the face, reminding one of the smell of a hive of heather-honey in Soptember."—(Cumming, Five Fears in Southern Africa.) They congregate in herds of from twelve to twenty; though at times as many as thirty, and even

forty, have been seen in company.

CAMEO, kim'-e-o (Ital. cammeo).—When gems are cut
in relief, they are called cameos; but the term is generally given to small sculptures executed on those precious stones which have two layers of different colours. The exterior of these layers forms the relief, and the interior the background. Imitation cameos are also made from shells, some of which are exquisite works of art. The shells generally employed are the bull's-mouth, which give a pinkish-white relief, with an underlayer of red, resembling the sardonyx. The underlayer of red, resembling the sardonyx. The black-helmet gives a dark onyx ground, and the queen's-conch a deep pink. As these shells have tarse layers of colour, the tints required for the different figures and representations can be toned and Cameca are also made of artificial submodified. Cameos are and more of assume the stances, and glass was employed for this purpose by the ancients. The origin, however, of cutting cameos in precious stones is very remote. The art is supposed in precious stones is very remote. The art is supposed to have had its line in Asia: it was practised in Babylon, and was transferred thence into Egypt by the Phomicians. It was then carried on by the Greeks the Fucancians. It was ton carried on by the Greeks and Romans, who broughtit to great perfection. After the age of Praxiteles, the art of cameo-cutting became very popular in Greece. They were not only used for ornaments of dress, but were set in goblets, vases, lamps, &c. Antiquarians have not decided as to whether the gems commonly called Etruscan are Greek. Some drinking cups at that time were made out of a single stone, the outer surface forming one cameo. The Genzaga cameo, now in St. Petersburg, is said to be

the fincet specimen of the entique cameo in sti It represents two heads, supposed to be those of It represents two heads, supposed to be those of Pa-ciny and Rurydies. A cameo, representing Cupid as Psyche, in the Marlborough collection, is said as he is finest in Bugland. The Portland wase in the Briti-Museum is one of the most beautiful specimens of a ancient glass cameo. The manufacture of shell came is very recent. It originated in Rome in 1895, and, it to the year 1840, was almost entirely confined to itsel A large number of cameos are now made in Pari-thoy are act, as brooker wine to and over the case of the process of of the proces they are set as brooches, pins, &c., and much wors ornaments.

CAMERALISTICS, kām'-s-rill-is-tiks (Ital, com-ra, a chamber), is a term sometimes employed to fiesignuse the science of public finance, or that branch of political economy which comprises the means of raising and disposing of the public revenue.

CAMERA LUCIDA, kām'-s-rā loo'-s-dā (Itat., light chamber), an optical instrument intended to facilitate the nervenotics delivation of chiefs invented by The

chamber), an optical instrument intended to seminate the perspective delineation of objects, invented by Dr. Wollaston in 1807. In its original form, the examera consists of a four-sided prism of glass, set in a brasiframe, which is supported by an upright rod six or eight inches long, having at its lower end a sorest clamp for fixing it to the edge of a table. The upper The upper face of the prism, which is placed horizonfally, and that directed towards the object to be delinested, form a right angle, and the other two faces form as obtuse angle of 135°. The rays from the object, falling nearly perpendicularly on the first surface, enter the prism, and are totally reflected by the lower and back prism, and are totally renected by the lower saw cooks surfaces to the eye, so that the object appears in the direction of the drawing-board, or table, placed beneath the instrument. The eye is placed at the edge of the prism, so that the rays from the drawingpencil and paper may enter the pupil together with the reflected rays from the object. In this way the draughtsman obtains a faint image of the object on the paper, and if he be skilled in the use of the instrument, he may trace the outline of the object with extraordinary lidelity. A plate of metal, with a small aperture as an eye-hole, is placed at the edge of the prism under the eye, so that the reflected rays and those from the sketching-point form only very small pencils. By thus cutting off the unnerman. cessary rays, the difficulty of using the instrument is greatly diminished, for the eye is kept to one point. There are various improvements and modifications of the camera lucida, the best of which is that contrived by Signor Amici of Modena, in which a triangular prism is combined with a plate of glass having parallel surfaces. The camera lucida has been most successfully employed in delineating the forms of wonder and beauty revealed by the microscope, instrument used for this purpose resembles that commonly applied to landscape-drawing, but is provided with a fitting, which adapts it to the eye-piece of the microscope. The steel disc of Sommering is used microscope. microscope. The week and of commercing is used by many microscopic draughtsmen instead of the camers. This contrivance is a little disc of polished steel, placed at an angle of 45° with the eye-piace, so as to receive the magnified image of the object and reflect it upwards upon the retina of the observer. The disc is smaller than the aperture of the pupil, and the drawing-peucil can at the same time be seen very well as it traces the image apparently thrown down on the paper beneath. When either the camera or steel disc is used, the body of the microscope must, if possible, be placed horizontally.

CAMERA OBSUEA, kām'-e-rā obs-ku'-rā (Lat., dark chamber), an optical instrument for producing upon a screen the image of a field of view more or less extensive. It was invented by Baptista Porta in the 16th century. It has long been known as a familiar toy, in which form it consists of a rectangular box, furnished at one end with a convex lens, having a focal length equal to the length and depth of the box. Opposite the lens is placed a plane mirror inclined at an angle of 45°, which throws the image of any object to which the lens may be directed image or any object to which the sens may be directed on a plate of ground glass at the top of the box. The image thus formed may be traced on the rough surface of the glass by a black-lead pencil. The glass is shaded from the external light by a hinged lid having two side wings. Since the discovery of photography, the camera has become an important scientific instrument, and has

Cancering

Cancering shopted the title of the Reformed Presbyterian Church. When Charles II., after his restoration, attempted to establish episcopsey in Scotland, many of the inhabitants of that country held that he had broken faith with the ation, and had forfeited all claim to their obedience. Some of the more prominent of these were persecuted and imprisoned, and not a few of them suffered marsmo imprisoned, and not a few of team same that they by dom. Bichard Cameron and about twenty others publicly issued a declaration at Sanquhar, and affixed it to the market cross, as a protest against the king and his government. Some weeks afterwards, the party was surprised by a vastly superior force in Airdsmoss, on the confines of the counties of Ayr and Dumfries. After a brave fight, Cameron and his brother were causer a prave ngnt, Cameron and his brother were sains, and sixteen others were taken prisoners, and soon after perished on the scaffold. Their principles, however, continued to gain ground, and in 1681 they organized themselves into various societies, maintaining close correspondence with each other. They still continued the objects of the most ruthless persecution. They were proscribed and hunted like wild beasts by the government, no respect being shown to either age or sex, while numbers of them perished on the scaffold or at the stake. Their leader, James Renwick, who was beheaded in 1888, was the last of the Scottish The Revolution, which occurred soon after, martyrs. The Kevolution, which occurred soon anter, put an end to their persecutions for conscience sake. They were among the first in Scotland to take up arms in the cause of the prince of Orange, in which they rendered important services, and were "the first men in Scotland that petitioned the Convention of Estates arms of Scotland on the head of their deliverer, king William." After the Revolution, and principally on account of the control exercised by the principally on account of the control exercised by the state in church matters, they were unwilling to unite with the church as then established in Scotland, and they remained a distinct body. They were never very numerous, and after this time they sank into a comparatively obscure sect. They did not form themselves into a regular church till 1743, when, under the direction of the Rev. John McMillau, who had joined them from the established church, they "formed and established a prebytery in the name of Christ, the alone king and head of the Church, under the title of the Reformed Presbytery." After this time they increased in numbers, and in 1811 a synod was constituted, under which there are six presbyteries, with 36 ministers and 45 there are six presbyteries, with 36 ministers and 45 congregations. The entire number of members is estimated at about 6,000. They have a theological hall, with professorships of systematical theology, and bib-lical literature and church bistory. The standards of the church are the Westmaster Confession of Faith, the larger and shorter catechisms, and a "Testimony," authorized and issued by the synod in 1839.

CAMERONIAMS, or CAMERONITES, the name also of Cavinists in France, so called from their foundar, John Cameron, a learned theologian, born nt Chasgow in 1579, and afterwards professor at Bordesux, Sedan, and Saumur. They asserted that the will of man is only determined by the practical independ of the mind, and that divine grace moves the will through the light imparted to the judgment. The rigid adherents to the synod of Dort were the rigid adherents to the synod of Dort were the rigid adherents to the synod of Dort were the rigid adherents to the synod of Dort were the rigid adherents to the synod of Dort were the rigid adherents to the synod of Dort were the rigid adherent them, and the controversy was arried or with great seal and subtlety on both sides, the camp was laid out round this spot. It was in the form of a square, and the length of each side the synonymetric product of the position of the position of the rigid adherent synonymetric products and the camp was laid out round this spot. It was in

whether the will of man is determined by God in diately, or mediately by the intervention of knowledge which he imparts to the mind.

CAMBARDS, kime-sards', the name given to the Pro-testant insurgents in the Covennes, who, after the revocation of the edict of Nantes, in 1685, being sub-jected to great persecutions, took up arms in their own defence, and for a time reprised upon their persecutors with equal cruelties. The name is said to be derived from comise, or chemise, a shirt, because, when making their nocturnal attacks, they usually wore a kind of shirt over their clothes, in order to distinguish each smir over their clothes, in order to distinguish each other; hence camisade signifies a nocturnal attack. After seventeen years of suffering, they at length, in July, 1702, took up arms in their own defence, and, incensed by the speeches and prophecies of some among them who pretended to be inspired, their seal rose to fanaticism. Severe measures were adopted against them; their villages were burned and their prisoners butchered; and they, in turn, pillaged and burned the Catholio villages, sacked the churches, and massacred the priests. Marshal Villare having, in 1704, succeeded the Marshal de Montrevel, who was first sent out against them, tried pacific instead of harsh measures, and by persuasion and promises induced many of them to lay down their arms; among whom was Jean Cavalier, the ablest and most popular of their leaders. This remarkable man, originally a journeyman baker, afterwards came to England, where he was favourably received, and rose to be a general in the army and governor of Jersey. The recusant Camisards continued in arms for some time; but, being much reduced in strength, their attacks were being much reduced in strength, their attacks were less frequent, and on a much smaller scale, and by degrees hostilities ceased. A subsequent rising took place in the Vivaraia, a part of the Cevennes country, in 1709, which, after a vigorous resistance, was subdued. A work on the Camisards has recently been published by Ernest Alby (Paris, 1835).

CAMLER, käw'det (from camel), was the name originally given to a fine cloth made from the hair of the Angora goat. The British camlets are, however, entirely made of sheep's wool, or a mixture of wool with linen or cotton, and spun very hard.

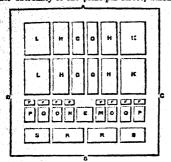

entirely made of sheep's wool, or a mixture of wool with line or cotton, and spun very hard.

Camomile, or Chamomile. (See Anthemis.)

Camourler, kām-oo-flai.—In Mil., when sappers and miners have driven a gallery close to any part of the works of a besieged town, a countermine is some times made by the besieged, charged with a composition so called, the explosion of which destroys the works of the attacking party, and kills or injures the men em-ployed in the trenches with its intolerable and suffocating odour.

CAMP, kamp (Lat. campus, a level plain), the name applied to any collection of tents or huts in which soldiers are temporarily lodged in time of war, or to buildings of more lasting character; as the camps at Aldershot and the Currugh. The children of Israel are spoken of in Numbers ii. as pitching their camp, according to their tribes, round the tabernacle in the wilderness; and this is the first mention of a military encampment in history. The Romans paid great attention to the formation of their camps. Wherever tention to the formation of their camps. Wherever the army remained, if only for a single night, a trench was dug, and a rampart thrown up round it for its was dug, and a rampart thrown up round it for its protection. They were acoustomed to make two different kinds of camps,—one for the summer easson, when troops were on the march, and the other for soldiers in winter quarters. They were slike in principles of construction, but, while the summer camps were larger in size, being intended for the accommodation or an entire consular army, the winter camps were more strongly fortified. When a Roman army was on the march, some centurions, with a military tribune, were usually sent on before the main body to choose a site and mark out a camp for the encampment of the army for the ensuing night, or for a longer period, as it might happen, The ground chosen was generally as level as possible, and on elevated ground, from which the whole of the

# was about 2,080 English feet, when it was intended to secondare an entire consular army, which consisted of two Bonan legions, each of 4,200 foot-soldiers and 500 cavalry, and 10,500 infantry and 1,800 cavalry of allied or suxiliary troops, of which 2,100 infantry and 600 eavalry formed what were termed the extraordinary or picked troops of the alines, who acted as part of the general's body-guard; making the total force under arms about 25,000 men, including officers. There was a gate in each side of the square; namely the Printerian gate (A), in the front of the camp, the Decumn (n) in the rear, and the principal gates (C, D) at sither extremity of the principal street, which ran

BOMAN CAMP.

through the camp in front of the Prætorium (E), and was 100 feet in width. The tents of the tribunes, who held the chief commands in the Roman legions, and the prefects, who were possessed of equal authority the prefects, who were possessed of equal authority among the auxiliary troops, were placed along the principal street on either side of the general's quarters, but slightly in advance. A road 50 feet in breadth ran from the Pretorium to the Pretorian gate, crossed about midway, at right angles, by another called the Via Quintana. On either side of the passage to the Prætorian gate, the Roman cavalry were posted (G, G), and with them the Triarii, a division of the Roman interest fantry. (See ARMY.) Other passages of fifty feet inter-vened between the tents of these troops and those of vened between the tents of these troops and those of the rest of the Roman infantry  $(\mathbf{n}, \mathbf{n})$ , and also between these and the cavalry and infantry of the allies, part of which were placed on the right wing of the army  $(\mathbf{x})$  and part on the left wing  $(\mathbf{n})$ . On the right of the Præstorium were the quarters of the quæstor  $(\mathbf{M})$ , who acted as the chief of the commissariat department; on the left, the forum (N), or market. On either side of the questor's quarters and the market were placed the tents of the auxiliary cavalry (0,0) and infantry (r, r), that formed the consul's body-guard, separated by the quarters of volunteer troops, consisting of men of rank and station, who had accompanied the army out of friendship towards the general. In the rear of these of triendship towards the general. In the rear of these quarters and the Prætorium were placed the remainder of the chosen or extraordinary auxiliary troops (z, z), while the remaining space (s, s) was occupied by any friendly troops that might be attached to the army for a short time. Between the inner square thus occupied by the encampment and the rampart, an open space, 200 feet in width, intervened. The vallum, or rampart, was made of turf and earth taken out of the forea, or ditch, surmounted and strengthened by a row of stakes or palisades. The ditch itself was generally from twelve to lifteen feet wide and nine or ten rally from twenty to interest feet deep. In consequence of the arrangement above described being always adhered to, with certain necessary modifications, when required, according to circumstances, the troops composing a Roman army always knew the position they were to occupy; and as the camp was always marked out before the arrival of the main body, each cohort repaired to its quarters as ans main body, each conort repaired to its quarters as it came up, and immediately proceeded to construct that part of the rampart and ditch which full to its share. Regular watch and ward was kept during day and night, and the guards were relieved every three hours. There are many remains of Roman camps in Great Britain; and all towns the names of which end

# Campaign

in "obseter," a corruption of the Latin create, a canch as Manchester, Colchester, Windhester, Ec, been built on the sites of Roman emangements or tary towns, from which they have derived their as The remains of the Danish camps in this country those which are considered to be Danish, indicate they were circular in form, and sometimes constri with more than one line of defence. The tenus encampments of the Saxons and Danes were fortif with barricades composed of trees, with the branch cut, to present the form of projecting stakes, and son times with a rampart of earth and stones. The Briton times with a rampart of earth and stones. Let breaking protected their villages in a similar manner. The Gauls and ancient Germans surrounded themselves with their waggons and chariots, disposed in the forms of a circle, and strengthened by barricades of trees and branches. With regard to the disposition of and branches. With regard to the disposition of troops in these circular inclosures, it is known that the Saxons pitched the tent of their chief in the centre, and the cavalry were grouped immediately round it, while the infantry occupied the remaining space is tween the cavalry and the defensive barriers. Prior to the use of cannon, in the time of the Norman and early Plantagenet kings, it is supposed that English armies were encamped in the field on a plan similar in general principles to that adopted by the Romans, the ground being marked out and a position assigned to each eing marked out and a position assigned to each oeing marked out and a position assigned to each division. When an army was besieging a town, the camp was protected by fortifications to guard against surprise, and when cannon were introduced, redoubts were added at various points of the line of defences. But the practice of grouping the tents or huts in the form of a square or circle has been abandoned for some two centuries or more, to avoid exposing the army to the fire of the enemy in one mass; and it is now con-sidered better to place the tents along an extended front. sidered better to place the tents along an extended front, each regiment occupying the position it would take if the army were drawn up in order of battle (see Lines of INTLENCHMENT), and the tents not showing a greater extent in front than the regiment would occupy when drawn up two deep. A battalion 1,000 strong would therefore require a space in front of 875 feet for the extent of the line of tents, as it would occupy this space when drawn up in file. A regiment of cavalry of the direct proposition of eight troops of eights. space when drawn up in life. A regiment of cavalry drawn up two deep, consisting of eight troops of eighty men each, would occupy a front of 960 feet. The tents for the infantry are placed in two rows parallel to the front; the tents of the captains and subalterus occupy another line; and the tents of the field-officers, the sutler's tent, and the field-officers' horses, are grouned sutler's tent, and the field-officers' horses, are grouped behind these. The tents of the quarter-guard are placed about 250 feet to the front, in the centre of the battalion, and the tents of the rear-guard are pitched about fifty feet to the rear of the antier's tent. The regiment parades in front of the first line of tents, between these and the tents of the quarter-guard. between these and the tents of the quarter-guard. As somewhat similar arrangement is adopted for cavalry; but the tents of the privates are pitched in lines perpendicular to the front, instead of being parallel to its as for infantry, and the horses are picketed between them. When an army is encamped, the infantry is generally disposed in the centre in two lines, with the reserve occupying another line in the rear; the cavalry is placed on aither side and the arrillary is placed. is placed on either side, and the artillery is placed on the flanks with the cavalry, or in the rear. encompment is formed, great attention is always paid to the position of the ground around it, and all approaches are fortified against attack by redoubts and intrenchments. Advanced guards are also throws out all round, to guard against surprise or sudden attack. Any good plan of the disposition of the British and French forces before Sebastopol, showing the nature of the ground and the position of the redoubts that defended the approaches, will give the reader the best idea of the arrangement of a modern camp, which must always be governed by the nature

camp, which must always be governed by the nature of the surrounding country.

CAMPAIGN, kim-pain (Fr. campagne, Ital. campagne, an open plain), a term applied in the present day to a series of operations in warfare, by which any important end is achieved. It was formerly taken to mean that which was done by an army between the time that it winter-quarters if active operations in the field during the summer months, until it entered them again. During this time the soldiers were under can-

s or without shelter in the open field; and hence

the name.

The name.

This camp, and the comp
state Curragh of Kudare, in Ireland, are permanent
earing, intended for the instruction of officers and
soldiers in military acience and operations in the field,
and to teach them how armies, divisions, and brigades
are handled in warfare, forming, in fact, practical
military schools on a large scale. For this purpose
the country round Aldershot is well stapted, being
composed of moorland, heath, and common, unfit for
stalivation, but admirably well suited for sham fights
and the construction of siege works and intrench
ments. The heath, which was purchased by government in 1854 for about £130,000, has an area of rather
more than 7,000 acres. The situation presents advantages of a peculiar nature in being near the London
and South-Western and South-Eastern railways, which
senders it convenient for the dispatch of troops to renders it convenient for the dispatch of troops to the southern shores of England at very short notice, should occasion ever require it. The camp was imme-diately laid out and drained, and roads formed; blocks of wooden hats were also constructed for the reception of the soldiers, which have since been replaced by brick berracks replete with every convenience, at a cost of more than £250,000, forming the finest barracks in the world. The buildings form two long lines, with a paradeground between them, the infantry and artillery occupring what is called the North Camp, and the cavalry the South Camp. The barracks are disposed in the form of blocks, or quadrangles, with a courtyard in the centre, each block affording accommodation for an entire regiment, and containing sleeping-rooms, each for twenty-four men, washing-rooms, mess-rooms, school-rooms, kitchens, and the necessary offices, with separate spartments for the sergeants and married soldiers. The officers' barracks and mess-rooms are situated in the spaces that intercene between the blocks. The sleeping-rooms have balconies attached, from which the men gain a view of the surrounding country and parade-grounds. Drill-grounds, covered in with glass, have been made, and suitable play-grounds, in different parts of the camp. Stables, and sheds for guns and stores, are attached to the artiflery and cavalry barracks. Lectures and amateur theatrical performances are given for the instruction and amusement of the men, and the only requisites to be added for the soldier's recreation are those of soldiers' alub-houses and gardens, to counteract the ill effects of beer-houses and other places of demoralization that abound in the neighbourhood.

CAMP EQUIPAGE, a term under which are included all necessary articles for the use of the soldier in the field, such as tents, tent furniture, and cooking uten-Both officers and men are restricted to a certain equantity of camp equipage, that the army may move from place to place with as little incumbrance as possible. (See Text.) The camp equipage of an army on the march in India exceeds that of all others, on account of the peculiar requirements of the eastern climate and the numbers of non-combatants that move with it. (See CAMP-FOLLOWERS.)

CAMP-FOLLOWERS, the name given to the sutlers and men and women who deal in trifling commodities, and follow an army on the march. In India there are often as many as five camp-followers for every officer sad soldier in the army. When in the field they are subject to the Articles of War. They prove of some utility in a battle for the purpose of conveying the wounded to the rear, or by assisting to do so; but the majority of them, the women especially, my for the sake of plundering the slain, often killing e wounded after nightfall, for the sake of the stebes, money, and jewellery that they may have out them. They will often purchase valuable articles shout them. They will often purchase valuable articles from the soldiers for small sums of money, and many here been known to acquire considerable wealth by

Care-Maxings are religious festivals held among Methodists in some parts of England and the United Bates of America. In the latter country, Presbyterians also, particularly in the back settlements, have their camp-meetings. In America, on these occa-sions, the people assemble from great distances, some

in waggons, others on horseback, sometimes to the number of 15,000 or 20,000. They bring their provi-sions with them, and, arecting booths, they dovote a to reight days to religious exercises. Besides prayerdaily during the festival, and the Lord's Supper is celebrated on the Sunday. In Mrs. Stowe's "lived" there is an account of an extraordinary camp-meeting. Among the Methodists of England the camp-meeting

only lasts for one day.

Campanile, kam'-pa-nue (Ital. campana, a bell), the
Italian name for a beliry or bell-tower, and thence applied in Arch, to any part of a nuturing the rest in the form of a square tower. The campanile differs from the English bell-tower in being denied differs from the English bell-tower in being denied in the belongs. There plied in Arch, to any part of a building that rises above tached from the building to which it belongs. are some good examples in modern English church architecture, the best of which will be found at Wilton, in Wiltshire, appended to the Byzantine church built by Lord Herbert of Lea. In domestic architecture, in which will be the control of the co ture the campanile usually rises over the entrance, terminating in a room of small size at the top, which often answers the purpose of a belvidere. (See Bri-Otten answers the purpose of a belvidere. (See BEL-NTBER.) The chimney-shafts of engine-houses are often built in this style. It is a distinctive feature of Italian architecture, and is found in Byzantine archi-tecture of the third period (see BYZANTINE ARCHI-TECTURE), as exemplified in that attached to the church of St. Mark at Venice. They are generally square in form, without buttresses, and of the same dimensions from top to bettom. The leaning tower of Pisa is, however, an example of the circular campanile. It was bogun in 1174 by Bounanus of Piss and William of Innspruck. It is 178 feet high, 50 feet in diameter: the summit is reached by 330 steps. The reason of was begun in 174 by hounants of riss and winds in finispruck. It is 178 feet high, 50 feet in diameter: the summit is reached by 330 stops. The reason of its being termed the leaning tower arises from the fact of its leaning 13 feet from the perpendicular. Among those which are to be seen in almost every Italian town, the campaniles at Cremona and Florence are most worthy of notice, the former for its great height (395 feet) and the latter for the great beauty of its design and execution. It was built by Giotto in 1334, and is 209 feet high, occupying an area of 45 feet square. The exterior is coated with slabs of coloured marble. It was the intention of the architect to have placed a spire on the top, but his design has never been carried out. There is a good campanile, \$50 feet high, attached to the cathedral of Seculle, built at the close of the 12th century, now caited La Giralda, from an enormous weathercock, a ton and a half in weight, cast in bronze, which was put up in 1565. It represents a female figure. female figure.

CAMPANILA, kām-pān'-u-lā (Lat., a little bell), in Bot., the Bell-flower, a gen. of plants forming the type of the nat. ord. Campanilacea. It includes several British spacies, which are known to all lovers of wild flowers; thus, C. rotuniifolia is the hare-bell; C. giomerata, the clustered bell-flower; and C. Rapunculus, the rampion. The roots of the latter species

are eaten in some parts.

CAMPANULACEA, kam-pan-u-lai-se-r, in Bot., a nat. ord. of dicotyledonous plants in the sub-class Corolli-flora, consisting of herbs, or undershrubs, with the following characters :- Leaves nearly always alternate, exatipulate; calyx superior, persistent; corolla monopetalous, regular; stamens equal in number to the lobes of the corolla, with which they are alternate: anthere 2-celled, distinct, or partly united; fruit err, capsular, opening by lateral fissures or valves at the top, many-seeded; seeds with fleshy albumen. There are 29 genera and 500 species, chiefly natives of the temperate parts of the northern hemisphere.

comperate parts of the northern hemisphere.

Campanularia, Campanularia, kām-pāgu-lai'-ria, a gen and fam of zoophytes. This division is thus characterized by Dr. Johnson:—"Palypedom plant-like, horny, rooted by a creeping tubular
fibre, branched or simple; the polypes cell this and
campanulate, terminal, elevated on a ringed footstalk
disposed either alternately or irregular." The above authority also mentions having seen the auteoms of a crab so completely invested with this zoophyte as to resemble hairy bruskes, the coralline in this instance having chosen a station by which it obtained all the hearlist of locametrics. benefits of locomotion.

414

CAMPBRILITIES, OF DESCIPLES OF CREIFF, Rawbel-ites, an American sect of Baptists founded by
Alexander Campbell, a Bootchman, who left the Pressysterian church in 1812. He became united with a
Baptist association, but, protesting against all human
creeds as a lond of union, and declaring that the
Bible slone ought to be accepted as the rule of faith
and practice, he was excluded from the fellowship of
the Baptists in 1827. His followers formed themselves
into a separate body, and in 1833 were supposed to
number 100,000 souls. In 1841 Mr. Campbell founded
a college at Bethany, in Virginia, which is attended by
about 150 students. The sect at present is supposed
to number about 150,000 persons, principally in the
states of Virginia, Tennessee, and Kentucky.
Camphene, a

CAMPHENE, CAMPHILINE, or DADYL, kim'-pheen, a product obtained from turpentine by acting on that body with hydrochloric acid. Hydrochlorate of camphene is formed, which is transformed into camphene by the abstraction of the hydrochloric acid by the aid

of quicklime.

CAMPHINE, kom-pheen', a name applied commercially to a pure variety of oil of turpentine which is said to be furnished by the Pinus australis of the

southern states of America.

CAMPROGENS, kim'-fo-jens, a series of hydrocarbons, which, when treated with hydrochloric acid, form artificial camphor or terebenes. They include oil of turpeatine, oil of lemons, oil of rue, and one or two

others.

CAMPROE, kām'-for (Gr. kamphogen, Arab. kaphoor), a solid crystalline substance found in many plants, though only obtained in large quantities from two; namely, Camonly outsined in large quantities from two; namely, Camphora officinarum and Dryobalanops aromatica. The former, an evergreen tree growing in China, Formosa, and Japan, yields almost all the camphor of European comerce. The camphor, which may be regarded as a solid volatile oil, is diffused through the entire plant, and is separated from the root, trunk, and brunches. These parts are out into chips, and boiled in water till the camphor begins to adhere to the stirring-rod, when the liquid is strained and allowed to stand until the complor concretes. It is then sublimed into inverted straw cones contained within the carthen capitals of the stills. Vast quantities of this crude camphor are procured from the province of Fokien, in China, and the opposite island of Formosa; but some of good quality exported from Japan. It is generally in small grey ish, slightly sparkling grains, which, by aggregation, form crumbling cakes. Refined camphor is prepared by mixing the crude product with line, and subliming it into thin glass ressels of a peculiar shape, which are afterwards cracked so as to obtain the camphor in concavo-convex cakes, each about three inches thick, with a hole in the middle. Camphor is colourless and transa hole in the middle. Campior is colouriess and trans-lacent, and has a strong, penetrating, aromatic odour, and a bitter, rather pungent taste, though leaving a sensation of coolness in the mouth. Its specific gra-rity is from '98 to '99; so that it floats upon water, and, evaporating while doing so, undergoes a curious rotatory movement. It rolatilizes slowly at ordinary temperatures, melts at 288° Fahr., boils at 400°, and burns with a bright flame. It is soluble in alcohol, ether, oils, and dilute acids; also to a certain extent in water. The Sumatra or Borneo camphor is the produce of Dryobalanops aromatica. It greatly resem-bles the ordinary camphor, but is never seen in Euro-pean commerce, because the Chinese give a price for it eighty or a hundred times greater than that at which they sell their own camphor. It does not appear, however, that the Sumatra camphor is in any way preferable to that of Chins. The same tree which affords this rare substance yields also a pale yellowish Impid fluid, called diguid camphor, or cumphor oil. Artificial camphor, closely resembling the natural product, many be formed by acting upon oil of turpentine with bydrochloric acid. It differs from true camphor in burning with a sooty flame, and in giving off, when mention, no donor of carpetonic. Campute is used in medicine, both internally and externally, as a temporary stimulant. In moderate doses, it will allay nervous triffaction and produce quietude and placidity of feeling. In very large doses it acts as # narcotic, and is said to be poisonous. Raspail, the founder of a peculiar system of medicine widely adouted in France, alevates wen of medicine widely adopted in France, elevates

camphor almost to the dignity of suniversal medicine. The alcoholic solution of camphor and liniments, of which it is the principal ingredient, are much used for external application in sprains and bruises, chilblains, and chronic rheumatism. Insects are kept from attacking specimens of natural history by placing places of camphor in the cases in which such specimens are preserved. Chemically considered, camphor is a compound of carbon, hydrogen, and oxygen, in the provotions avpressed by the fewards of

portions expressed by the formula  $C_{10}H_{\bullet}O$ .

Campriora, kinn-fo'-ra, in Bot., a gen. of plants belonging to the nat. ord. Lauraces. The most interesting species is C. officinarum, the camphoratese, a native of China, Formosa, and Japan, where it grows to a considerable size. It is an evergreen, and all parts emit a champhoraceous odour when bruised. The wood is white, light, and durable, and is much used in China for carpenter's work. From the roots, trunk, and branches of this plant, the common, or

parts emit a champhoraceous odour when bruised. The wood is white, light, and durable, and is much used in China for carpenter's work. From the roots, trunk, and branches of this plant, the common, or officinal camphor, is obtained. (See CAMPROS.)
CAMPHORIO ACID, kām for ik; is formed when camphor is acted on by concentrated mitric said. It crystallizes in lamellar or accounter crystals, which have a bitterish sour taste. They melt at 138° Fahrand dissolve slightly in water. Camphoric soid forms salts with the various bases.

salts with the various bases.

Camphenene, kam'-frome, a liquid formed by passing the vapour of camphor over red-hot lime.

Campion. (See Silkne.)

CAMPYLOSPERME, küm-pi-los-per-me (Gr. kampules, a curve; sperma, seed), in Bot., a sub-ord. of the Umbellifera, characterized by the alloumen of the seed being rolled inwards at the edges, so as to present a

vertical furrow on its face.

CANAILIE, kin-tle' (Lat. canis, a dog), is a French term sometimes used in this country, and signifying the lowest class of the people,—the rabble. Formerly, before the revolution in France, this word was applied by the nobility to all who were not of their own-rank; and afterwards the people themselves adopted it in contempt of the aristocracy, when it came to lose its offensive signification. At present, the French sp-ply the term only to such as have been guilty of some ase act. Of one who has degraded himself, whatever

his rank, they say, "C'est une canaille."
CAMWOOD. (See BAPHIA.)

CANAL, kān-āl' (Lat. canalis, a water-course), an artificial water-course made for the purpose of facilitating communication and the carriage of coals, bricks, and heavy goods, from a seaport to any inland town, or from one inland town to another. Some are broad and deep enough to admit of the passage of vessels of considerable tonnage, in which case they are termed "ship canals:" others are but limited in length, and merely intended to allow barges and small vessels to pass from one part of a navigable river to another, and thereby to avoid any shallows or irregularity in its course that tend to obstruct navigation, or to cut of "any bend of considerable extent;—these are called "lateral canals." Canals cut for the purpose of allowing the passage of boats from one river to another, each supplied by a different watershed, such as the Canal du Centre in France, are called "summit-level canals." All the great nations mentioned in the early history of the world were in the habit of constructing canals for promoting inland navigation. Remains of engineering works of this nature of considerable extent are to be found in India, Egypt, and the plains of Assyria, watered by the Tigris and Euphrates. The canals of the Chinese are of great length, the Great or Imperial canal, by which Pekin is supplied with rice, and the various productions of the provinces that lie to the south of it, is 700 miles long. It was not untall to have been introduced by Leonardo da Vinci in the construction of a canal near Milan. Up to that time and the construction of a canal near Milan. Up to that time and had merely been long lines of water of the same level throughout; but the contrivance known as the "look" allowed them to be many feet above the level of that next to the river or estuary with which it communicated, and admitted their construction of the last inland reach of any canal might be many feet above the level plains. In Holland, canals take the place of roads

real message; but the extreme fishness of the readers the use of the look less requisite than m parse of Europe. The first causi of any importance made in France was the Canal de Briere, which unites the rivers Loure and Seine, which was completed in 1642; but the greatest engineering work of this kind ever attempted in that country is the Southern senal, or canal of Languedoc, which connects the Mediterranean with the Atlantic Ocean, and allows the Mactiterranean with the Atlantic Ocean, and shows vessels of 100 tons burden to pass along its entire length. It is nearly 150 miles long, with upwards of 100 locks. It is carried over many valleys by means of adjudgments, and is 600 feet above the level of the sea in its highest part. This great undertaking was finished in 1661. In England, the construction of canals did not commence until the middle of the 16th century, igh the New River canal had been cut and complaced by the year 1614, and the Thames made navigable as far as Oxford a lew years later. Among the principal English canais may be mentioned the Bridge-water smal, constructed by Mr. Brindley for the duke of Bridgewater, commenced in 1758, and the Grand Junction canal, completed 1790, which communicates with several others, and affords inland communication between the ports of London, Bristol, Liverpool, and Hull, by the various capals and rivers with which it is connected. In America, the Great Eric canal, 363 miles long, is one of the most famous; and the Welland canal, which connects Lake Eric with Lake Ontario, and ena-bles reseals to pass from one lake to the other, which the Falls of Niagara would otherwise prevent. The Ganges canal, in India, cut for the purpose of watering the land between the Ganges and the Jumna, is the largest in the world; it is 900 miles in length, and, when com-pleted, will have cost upwards of £1,500,000. In late years schemes have been introduced for uniting the Atlantic and Pacific oceans by a ship canal across the Isthmus of Panama, and for cutting a canal through the Isthmus of Suez, to allow vessels en route for India to pass from the Mediterranean Sea to the Red Sea. M. de Lesseps, the projector and engineer of the last-named canal, commenced operations some years since, and his great undertaking was completed in 1869. In constructing the Suez ship canal, the Object sought was to unite the Mediterranean with of some thousands of miles which vessels proceeding to India or Polynesia are compelled to make. to inma or Polynessa are compelled to make. The Ishmus of Suez is a sandy valley some hundred miles in extent, more than half of it being in its natural state under water. Lake Menzaleh extends inland from Port Said, on the Mediterranean, for upwards of 30 miles; Lake Ballah extends for 10 miles; Lake Timesh and the Bitter Lakes have an extent of about 60 miles. There were thus only about thirty miles of excavations to be carried out. From Mr. Hawkshaw's report to the Egyptian government, we learn that the the to be performed upon the principal canal was as follows:—Commencing at Suez, a channel had to be dredged in sufficiently deep water. The mouth of this channel terminates to the southward of the entrance to the basin and graving-dock, constructed for the railway and steam-packet traffic. The portion dredged raiway and steam-packet trailic. The portion dredged averages 16½ feet deep. Between the upper edge of this dredged channel and the Bitter Lakes is a distance of 12½ miles, and the canal between these points is whelly in excavation, varying from 29½ feet to 55½ feet in depth. The canal traverses the Bitter Lakes for about 25 miles. It is next carried on to Lake Timash an agent. In a casal reverses the Bitter Lakes for about 23 miles. It is next carried on to Lake Timesh through an excavation 8 miles in length, the cutting through this distance varying from 294 feet to 62 feet in depth. It traverses Lake Timesh for a distance of 22 miles, the excavation at this point averaging about 25 feet in depth. At El Guier, which lies between Lake Timesh and Lake Ballah -- a distance of 112 miles, the canal enters the highest ground. The depth of the capting between these two lakes varies from 293 feet to 35 feet. From Lake Ballah to Lake Menzaleh, a distance of 21 miles, the excavation averages 294 feet. The canal then passes through Lake Menzaleh, and processes to Port Said, a distance of 20 miles, the excavations averaging at this part about 25 feet in depth. Port Said consists of a basin 375 wards square, and of an exestern and western stone jetty extending into the sea. The eastern jetty is a line work, 3,609

yards long from the covet-line, and the western je 2,515 yards long, the distance between the two bei 437 yards. The canal between flues and the Bits Lakes was originally intended to be 328 feet wide, and between these lakes and the Mediterranean 2622 wide. The width between the zwo latter prints was afterwards reduced to 190 feet. The width between the Bitter Lakes and Suez was also much reduced. The length of the canal from sea to sea is about 90 The cost of the undertaking was originally asti mated at £8,000,000; but as much more was required before the undertaking was half accomplished. only the harbour of Port Said, but the principal por-tion of the canal itself, had to be constructed by dredging; and this, in soft ground or through the aludge of Lake Menzalch, was sufficiently easy work. It was carried out in this way : the mud raised from the bottom was spread along each margin of the newly-scooped channel; but it would not remain there, and for a time the prospect of maintaining an open way seemed as hopeless as George Stephenson's open way seemed as noperes as usorge suspensions wifers attempt to carry the Liverpool and Manchester railway across Chat Moss. No scoper was the Menzaleh mud deposited in its new position, than it either slipped back into its former bed or squeezed the soft soil on which it lay into the channel. It was clear that if some means of getting over this difficulty were not discovered the Sacre Court and the same has the source of the source of the source of the same has the not discovered, the Suez Canal could never be com-pleted. It is said that a labourer one day hit upon a plan which saved the undertaking from failure. He showed that if, instead of laying the mud in great heaps, a thin layer were spread and left to herden in the aun, it would not alip back. Mr. Robert Stephenson, as well as other celebrated English engineers, held the opinion that the canal could not prove otherwise than a failure. Be this as it may, the canal is at the present moment completed, and perfectly open for ships; but whether or not it can be kept in proper working order, time alone can prove. An eminent writer states in Nature, that, in his opinion, the work will really endure. He says,—"Since the Suez Canal was first projected, engineering acience has advanced; and though the sands will accumulate at Port Said as from old, the piers and breakwaters will be periodically lengthened, - made to stretch further and further into the sea, while powerful steam-dredges will scrape away the sand from the mouth of the harbour. Whether heavy gales will effect any more serious choking of the approaches, or drift tons of blowing sand into the canal itself, remains to be seen." new route to the East makes the voyage to India eight thousand miles instead of the fifteen thousand by the old route round the Cape of Good Hope. Ship canals are generally short in length, being intended for the passage of vessels from the coast to towns situated at a short distance from it, or from one sea to another. Among the most notable of this description met by North Holland small between the Westlemann of the Cape of the to another. Among the most notable of this description are the North Holland canal, between the Holder and Amsterdam, and the Caledonian canal, between the North Sea and the Atlantic, connecting Beauly Firth, an arm of the Moray Firth, and locks Ness, Oich, Lochy, and Eil, with Loch Linnhe on the western coast, by means of cuttings from one to another. The former is 51 miles in length, 125 feet wide at the surface, 31 feet across the bottom, and 20 feet deep. It is below the level of the sea, but it is protected by embankments from any influx of the ocean. The looks are 297 feet long and 51 feet broad, for large vessels; but there are some of less size to admit of the passage of smaller vessels. Ships of 1,400 tons burden can pass through the larger locks. The entire length of the Caledonian canal from Beauly Firth to Loch Linnhe is 60 miles, of which 23 are artificial cuttings, and th remainder the intervening looks above named. The cuttings are 115 feet across the surface of the water, 50 across the bottom, and 20 feet deep; there are 26 locks in the course of the causi, about 175 feet long and 40 wide. The difference in level between each reach is about 8 feet. The entrance to a ship canal should be sheltered, and in such a position that it may be free from the deposit of mud and alluvial matter. The nature and construction of locks and lock-chambers for these and other conals will be found elsewhere. (See Lock.) Towing-paths are made on both sides, and are about three feet above the level of the water.

## Canal

The top of the chelring bank on sister side is sut in this form of a step, to leave a few feet of shellow water between the man hody of water in the centre and the towing-paths on the sides, to break the action of water against the banks. The slope of the sides differs in different causals, but can easily as calculated from the dimensions of the depth and breadth at different points, as may be seen by reference to the annexed figure, which shows a section of the Caledonian canal Lateral canals are used as a means of affording a

SECTION OF THE CALEDONIAN CANIL

remedy for defective navigation in a river, they are similar in general principles to the ship causal and ordinary causal for barges but as the natural course of the river itself is made available for the passage (i) vessels in some parts, works of a peculiar construction are required to allow barges to pass from the river to the canal, and over error, or firm one side of a river to the other, which is often uccessary to avoid interference with another stream joining the main river below the point of transit. Sometimes it is contrived to carry a canal over any large tributary by m ans of squeduct the dimensions of the lateril canal of the Lorre, one of the best of its class are as fol-lows:—Breadth ack as the surface of the water, 33 feet, depth 5 feet 3 inches length of locks 100 feet breadth, 17 feet I he breadth of or linary bar, e canals in England varies from 16 to 50 feet across the water line, and the depth ranges from 1 to 6 feet 11 e floor line, or bottom, is rather more than twice the breadth of the largest boat likely to be used on the caual. The angle of inclination of the sides to the lotten varies angle of inclination of the state states and the state of slope, to receive shallow water but the segentrally neglected. The edge of the bank is sometimes neglected the edge of the bank is sometimes strengthened by a low parapet to prevent injury from the perpetual chafing of the tow ropes and ly paying or camp sheeting, to protect it from the wash it the waves caused by the passage of vessels. The towing paths vary from 4 to 16 feet in width accordingly as the towing is effected by means of men or horses. When it is necessary to cut a tunnel for the passage of a canal, a narrow space is sometimes allowed for a a county is nervow space is sometimes amoved for a towing path on one or both sides but when there are no towing paths, the bargemen force their boats through by lying on their backs on the top of the cargo and pushing against the top of the tunnel with their feet. Sometimes the barges are bauled through there lees Sometimes the Darges are handed through by pulling hand over hand along ropes fixed at either end of the tunnel, and in other cases, by machinery especially adapted for the purpose. Those are the old-fishnoned methods but, at the present time, a steamer is used upon the Regent's Canal and several extension. steamer is used upon the Kegen's Canal and several other canals. The bottom and sides of canals are made impermeable to water by coating them with a thick surface of puddle,—a mixture of loam or clay, gravel, and water, which is worked with a space until it will ne'ther absorb water nor adm t spaces until it was necessary as concrete as used instead of puddie, particularly by the French in addition to thus, and the construction of locks and works for communication with rivers, as in lateral canals, the saginess must be careful to secure an ample supply of water from natural and artificial sources, supply of water from natural and artificial sources, such as reservoirs, particularly in the construction of samphit-level canals, and to construct basins, wharfs, addings, and intermediate stations, to facultable the passage of vessels and the loading and unloading of Sheir cargoes. He has also to build aqueducts to darry the canal across valleys, and approx-aqueducts and sulvests (see Struck-Aqueduct, Oulvern) for

Camer, or Camerus (fast. comm., a reed), is applied a many parts of the human body. Canadis arteriouse is the focus, which unites the pulmosary artery and the aerts, but which disappears after iris. Canadis concerns, a canal which in the focus savers the shoot from the vera ports of the liver to be examining wone care. Canalis nusulis, a canal canadistic the internal canthus of the eye downwards.

Carrier, ka-new, a term recently adopted by us from the French, in which language it signifies a duck. This is it is used in a secondary sense, to denote a piece of information given out with the view of miscading, or in order to bring about some desirable result

CAPARIES, &dn-si-rees, in Mus., a lively dance-tune, in three-eight time, said to have been introduced into this country from the Canary Islands. It is, however, mose probable that it was carried over from Normandy to these islands by John de Bethencourt, who invaded them about the close of the 14th century. The Canaries is introduced by Purcell in his " Diocletian:" the tune is in two strains of eight bars each, in three-eight time.

CAPARTUM, kh.nai ri.um, in Bot., a gen. of plants belonging to the nat. ord. Ampridacem. The species are natives of the Spice Islands and parts of Asia. C. commune is cultivated for sake of the kernels of its fruit, and for the fragrant resinous substance which exudes from its bark. The latter probably constitutes the Manilla Elemi of commerce. C. microcarpum yields an oil very like copaiva, known in shipbuilding vards as Damar. Other species produce edible fruits, useful oils, and resins.

CANARY BIRD, ki-nail-re (Carduelis canaria).—This popular and pretty singing-bird is a native of the Canary Islands. Its introduction into Europe was comewhat singular. According to some authorities, at the end of the 14th century, and to others, at the end of the 16th century, a vessel containing, among other merchandise, a number of canary-birda, and which was bound for Leghorn, was wrecked on the

LONDON CANARY.

coast of Italy. The birds, being set at liberty, took refuge in the adjacent island of Elbs, and the climate being congenial to their habits, they increased con-siderably. The islanders, finding such an elegant suggests anddenly settling in their country, were anxious to become possessors of them, and quickly the whole colony of canaries were taken prisoners. From

# Cancelling of a Deed

greet; whereas, in the domesticated essary, we have a great variety of colours,—green, yellow, white, brown, grey, &c. This is, of course, owing to the sumerous cross-breedings this species has been subjected to. It broods freely with several other species; the goldfinch, the builfinch, the sistin, the green-bird, and the linuse, among the number. Altogether, it is reckened that there are no less than thirty varieties of the canary. The best authority on the subject say,—"Theoconaries that have the upper part of the body of a dusly green or linus-brown, and the under-nart the canaries that have the upper part of the body of a dusky green or linnet-brown, and the under-part the yellowish green of the green-bird, with dark-brown cyes, are the strongest, and most nearly resemble the primitive race. The yellow and the white have often red eyes, and are the most tender. The chestaut are the most uncommon, and hold a middle rank for strength and length of life between the two extremes. strength and length of life between the two extremes. The canary that is most admired smongst us now is one with the body white or yellow; the head (particularly if created), wings, and tail, yellowish dun. The second in degree is of a golden yellow, with the head, wings, and tail black, or, at least, dustry grey. Next follow the grey or blackieh, with a yellow head and collar, and the yellow, with a blackish or green tuft, both of which are very much valued. As for those that are irrespulsive spetted anachied or variegated tuft, both of which are very much valued. As for those that are irregularly spotted, speckled, or variegated, they are much less sought after, and are used to pair with those of one colour,—white, yellow, grey, browngrey, and the like."—(Bechstein's Cage-Birds.). In Germany and the Tyrol the breeding of this bird is carried on on an extensive scale, and it is principally from these places that the rest of Europe is supplied. In its mixture hours, the conversion of the property of the property is not because of the property of the proper In its native home, the canary builds its nest in thick, bushy, high shrubs and trees, with roots, moss, feathers, hair, &c.; pairs in February, lays from four to six pale-blue eggs, and hatches five and often six times in paie-inte eggs, and maches are and order at takes as the scason. Bechatein gives the following directions for getting and keeping good canaries:—"The most essential is to choose from among the young that which promises a fine tone, and to seclude it from all other birds, that it may learn and remember nothing bad. The same precaution is necessary during the first and second moulting; for, being likely to relearn, if I may say so, its song, it would introduce into it, with may say so, its song, it would introduce more of more equal ease, foreign parts. It must be observed whether the bird likes to sing alone or in company with others; for there are some which appear to have such whims, iking to hear only themselves, and which pout for whole years if they are not humoured on this point. Others sing faintly, and display their powers only when they can try their strength against a rival. It is very important to distabute regularly to singing-birds the simple allowance of fresh food which is intended for the distance of the desired. the day. By this means they will sing every day equally; because they will cat uniformly, and not pick the best one day, and be obliged to put up with the refuse the next. About two spoonfuls of dry food is sufficient for the daily nourishment of a causary."

CANARY-GRASS. (See PHALARIS.)
CANARY WINE.—This wine, which is also known by the name of Teneriffe, is a product of the Canary Islands. In taste it resembles Madeira; it is made from grapes which have been gathered before they are ripe, and, when new, has a sour and unpleasant teste. After being kept carefully for two or three years, its mildness increases greatly, and, like Madeirs, it is greatly improved by a journey to the tropics. More greatly improved by a journey to the tropics. More of it is produced on the island of Tenerific than on the other Canary islands. The name of Canary is only applied to the Bidogne wine, and never to the Malvoise or Malnesy of the Canaries.

CANCELLABIL, kin-sol-lai-red, the name given to an inferior class of servants of the church in the earlier part of its history, but the precise nature of whose duties is doubtful.

CANCELLI, kausel' li (Lat., lattice-work), in Med., is applied to the spongy or reticular substance of the

bones. (See BONE.)

CANCELLING OF A DEED, kin'-sel-king, is a delivery
of it up to have lines drawn ever it in the form of wance colony or canaries were taken prisoners. From of it up to have lines drawn over it in the form of finite they were brought to other countries, and became lattice work or cancelli, though the phrase is used highly raised as singing-birds. The wild bird of the figuratively for any manner of obliterating or detacing Canar stands and the demesticated bird so familiar in this nontry are quite at variance in personal approximate. The polour of the wild canary is a dusky rally speaking, the effect of a dead can only be designed.

the sodin de. rives its pame although it is many centuries since the constellation and sign occupied position. The sodiacal division so called occupics the thirty degrees of the ecliptic between 60° and 120° from

the first point of lines, or the vernal equinox. The most conspictions star in the constellation is Acubens, a star of the third magnitude.

CANCER (so called from the large blue veins which appear, in esacer, to resemble orabs claws), is a disease of a very malignant character, making its upearance as a seirchous tunour, which ultimately terminates in au ill-conditioned and deep ulcer. Any part of the body may be the seat of this disease, though the giands are most liable to its attack. The female breast, the tongue, or lips, are among the parts most subject to it. The tumour at first is small, hard, indolent, and nearly insensible, with little or no disco-location of the surrounding skin. It remains in this state for a longer or shorter period, sometimes for rears, but at length it passes into a more active con-dition:—the tumour increases in size, the skin changes the timour increases in size, the same changes to be felt in it. The pain, which is of a shooting or lamonating nature, is at first slight, and occurs at considerable intervals; but it increases by degrees, and the intervals diminish until it becomes almost constant. The currently in the constant of t tancous veins become turgid, and the surface of the turnour presents to the feel a knotty, uneven surface. Sometimes the skin never actually breaks, but usually, after a longer or shorter period, the tumour ulcerates and becomes an open sore. The discharge is of a thin, fixed, herid nature, which corrodes the surrounding parts. The sore presents thick jagged edges and a soft centre, easier as it were into irregular cells. The shooting pains are now much increased, and are of a very riolent nature. The disease pursues its onward course; sometimes it seems as if it had exhausted itself, and was allowing nature to work a cure by the formation of reas flash, but this is morally a delivation. formation of new flesh; but this is merely a delusion, for it soon recommences its destructive course, and at length, it may be after years, it series upon some vital organ, or the patient sinks exhausted by the pain and continued drain upon his system. Of the cause, nutrition of the continued drain upon his system. Of the cause, nutrition of the continued drain upon his terrible disease little is, unfortunately, known. By some it is regarded as continued by other as lead to the continue of the continue amfortunately, known. By some it is regarded as constitutional, by others as local; some maintain that it is hereditary, others that it may be transmitted by inscellation. So far as may be judged from the conflicting evidence on these points, there does seem, in general, to be a certain constitutional predisposition to this disease; though, according to Mr. Paget, only a sixth of the cases can be traced to any hereditary transmission. The evidence is against its being transmitted by incoulation. If cancer be at any period merely a local disease, it can only be in its earliest stage, for, In a short time, the whole system seems to be infected with it; and hence it is that, after a time, the extirpation of the original tumour so often fails in effecting a complete cure. Though all ages and both sexes are a complete cure. Though all ages and both sexes are lipble to this disease, the young are less frequently attacked by it than the old, and females are more substacked by it than her out, and remains are more sup-ject to it than majes. Though canger is, sufortunately, by no means uncommon, it is not all, nor even the majority of tumours, that bear a general resemblance to it, that are emicarous; in fact, it is often with the

ciating agony The only ho pating the tumour in its east after all, frequently affords. According to Mr. Paget (L. logy), the average duration of life of the cancer is forty-nine month in which the cancer was once re the average duration of life was so forty-nine months; and hence he average duration of life is not man the removal of the local disease, but probable that the progress of the mo-retarded by the operation. Sometim the knife, escharotics, as chloride of course to, but with no better success may not be expected, much good may means of palliatives; the patient is to 1 good nourishing diet, but all stimule avoided, and everything that would i the activity of the disease. The state health is to be carefully attended to, and body kept as free from excitement the local treatment of the disease, seda lock, henbane, and optum, are to be had seen order to allay the pain. Among the lower of disease is not of unfrequent occurrence, most liable to its attack being the dog and a

CANKER, kank'er (Sax. conore; Lat. concer), a disease in trees which attacks the young shoots and branches first of all, and at last appears in the trunk. If not cured or its progress prevented by cutting back the tree, that it may throw out new branches, it will gradually destroy it in the course of a few years. It is produced by accidental intery to the branches, or by superabundant moisture about the roots, that astiff subsoil will not allow to drain away. The usine is also subsoil will not allow to drain away. The name is also given to a disease which appears in the feet of horses and in the ears of dogs. In the horse it is produced very often by damp and dirt, but in some cases it is constitutional. Unceration takes place between the outer casing of horn and the tender part of the foot which the horn protects. It is attended with considerable inflammation, the horn becomes detached in parts, and proud flesh is formed. The portions of horn that are separating from the foot should be removed, and the sore dressed at first with a caustio preparation to stop the growth of proud flesh, and atterwards with Friar's bulsam. Until a cure is effected, the foot should be protected with tow, which should be changed: daily. Care should be taken to keep the foot clean and dry. In dogs, inflammation of the car produces ulceration and the formation of proud flesh in the interior of that organ. Bathing with warm water will often check the disease; and if this will not do, Goulard's lotion should be applied, to which a little shum may be subsequently added to heal the ulors. In some cases the disease appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the flat at the same appears at the edge of the edge of the edge of the edge of the disease appears at the edge of the flap of the ear, when means must be taken to prevent the deg from irritating the sore by scratching, and it must be dressed with an ontiment in which a fair proportion of alarm has been mixed.

meria, from its resonablance in appearance and propor-ties to ordinary commercial turnieria, is said to be the produce of C. escalara. The sends of C. indica are commonly called Indian shot, on account of their black colour and peculiar hardness.

colour and peculiar hardness.

OARNABIFACE's, kin-nd-bi-suc-se-s, in Bot., the Houp farm., a nat. ord. of plants of the selast Dicotyle-dosse, sub-class Mosachianydes; consisting of rough herbs with a watery fulce, having the following structural characters:—Leaves alterrate, lobed, stipulate; flowers small, unisexual, directous, the males in racemes or panicles; calyx scaly, imbricated; stamens 5, opposite the sepals, with thread-like filaments, the females in spikes or strobiles, each flower with one sepal surrounding the overve, which is superior and I-celled, conspiles or strobles, each nover was one separate ing the oversy, which is superior and I colled, containing a solitary pendulous ovale; fruit indehiscent; seed without albumen. There are only two genera, Canaghis and Humulus, the Hemp and the Hop, and each consists of but one species. They are natives of

oson consists of Duc one species. They are natives of the temperate parts of Europe and Asia. CARRADIS, kin'-ni-bis (Lat.), in Bot., the Hemp, a gen. of plants representing the nat. ord. Connabinacen.— Connabis sativa, the only species, yields the valuable fibre called hemp, which has been known for more than 2.500 rears as a material becomes than 2,500 years as a material for cordage, sacking, and cloth. In Britain the plant grows to the height of about six feet, but in warmer climates it has occasionally been found eighteen feet high. The principal supplies of the fibre are derived from accounting fruits, commonly termed hemp-seed, are oleaginous fruits, when and demulcent, and are used for feeding birds. submitted to pressure, they yield about 25 per cent. of a fixed oil, which is used for making varnishes. In the sap of the hemp-plant there exists a resinous substance which has extraordinary narcotic properties. In northern climates the proportion of this resin in the several parts of the plant is so small as to have escaped general observation; but in the warmer regions of the East, the resinous substance is sufficiently abundant to exude naturally from the flowers, leaves, and young twigs. The Indian hemp, which is so highly prized for its narcotic virtues, is considered by some botanists to be a distinct variety, and is distinguished by them as C. sation, var. indica. This berb, and the resin obtained, are largely employed in Asia, and in some parts of Africa and South America, for the purposes of indul-gence. The whole plant dried is known by the name of ganjah in the markets of Calcutta. The larger leaves and seed-capsules separated from the stalks are called bung, subjec, or sidhee. The tops and tender parts of the plants, collected just after the flowering time, are in some places soid under the name of huschisch. The dried thovers, galled kief in Morocco, contain so much of the narcotic principle that a small pipe filled with them, it smoked, will suffice to intoxicate. The dried night of the drawn and the contract of the dried night of the drawn and the contract of the dried night of the drawn and the contract of the dried night of the drawn and the contract of the dried night of the drawn and the contract of the dried night of the drawn and the contract of the drawn and the contract of the contract of the drawn and the contract of the drawn and the contract of pistils of the flower enter into the composition of the Turkish madjoun. The resin which naturally exudes from the leaves and flowers, when carefully collected from the leaves and howers, when carriany conserved by hand, is known as momeou, the same, when beaten off with sticks, is sold under the name of cherrus. An extract obtained by the use of butter, when mixed with spices, forms the dawanese of the Arabs, and is the foundation of the handlisch of many Eastern com-rises and districts. The dried plant is smoked and tries and districts. The dried plant is smoked, and sometimes chewed. Five or ten grains reduced to powder are smoked from a common pine along with ordinary tobacco, or from a water-pipe with a peculiar variety of tobacco called tombeki. The resin and resinous extract are generally swallowed in the form of pills or boluses. The hemp-plant and its preparations appear to have been used from very remote times. effects of the natural resin or churres have been carefully studied in India by Dr. O'Shaughnessy. He

working into ornaments like jet.

CANTRALS, kint mbils, is supposed to be scorring-tion of Caribs, the original inhabitants of the West-India islands, who were reputed to be mon-eaters; and hence the term has come to depote anthropological or persons who devour human flesh. Sometimes pe sons have been driven by dire necessity, as in s and shipwrecks, to eat human flesh; and there have even been instances known of persons in civilized countries with tastes so deprayed as to manifest a eraying tries with tastes so deprayed as to manager a confer for that kind of food, and to commit marder in order to obtain it. Many persons, however, have doubted whether there ever existed, in any state of acciety, a conference of the species with the species of the people who were voluntarily addicted to this species of barbarity; but the testimony of modern travellers, as well as of ancient writers, is so strong upon this point as to leave little room to doubt that it has been, and even still is, practised among various races. Homer represents the Cyclops and the Laestrygons as unthrepophagi; and, according to Herodotus, the Massagets ate the flesh of their aged parents. Herodotus also asserts that the Paden of India were in the habit of killing and eating their relatives when they fell ill; and that, snong the Essedones, when they had that, snong the Essedones, when a man's father died, his relations came and helped to eat the dead man, whose flesh was rendered more palatable by being mixed up with that of animals. Such accounts as these have been fully borne out by the descriptions of modern traveliers. The statements of Marco Polo of modern travellers. The statements of Marco Fold regarding the Battas, a people of Sumatra, have been confirmed by Mr. Marsden. When America was dis-covered, this practice was found to prevail to a very great extent. According to Prescott, they (the Mexicans) did not eat human flesh morely to gratify a brutish appetite, but in obedience to their religion "they (the Their repasts were made of the victims whose blood had been poured out on the altar of sacrifice." The body of the sacrificed captive "was delivered to the warrior who had taken him in battle, and by him, after being dressed, was served up in an entertainment to his friends. This was not the coarse repost of famished ans trends. It is was not the coarse repast of annahuse cannibals, but a banquet teening with delicious severages and delicate vinuds, prepared with art and attended by both sexes, who conducted themselves with all the decorum of civilized life."—(Conquest of Mexico.) In New Zealand and many parts of Africa cannibalism was systematically practised, with some, human leak helius recorded as a great delicar and some present of the control o flesh being regarded as a great delicacy, and even pre-ferred to every other kind of food. M. Du Challin states that the Fans, a people of equatorial Africa, not only devour the bodies of captires but even the bodies of those who have died of disease, parchasing for that purpose the corpses of neighbouring triber, and disposing in the same way those of their own. He relates that "u party of Fans, who came down to the sea-shore, once actually stole a freshly-buried body from the cemetery, and cooked it and as it among them; and, at another time, a party conveyed a body into the woods, cut it up, and shoked the fiesh, which they carried away with them." Some of the cannibals are now said to disalay a considerable decree of tasks. Orientals its general effect is of an agreeable and cheerful character, exciting them to laugh, dance, and sing, and to commit various extravagenees. It, however, and the commit various extravagenees. It, however, excitable and quarrelsome, disposing them to acts of violence. It is from the extravalue of the commit various of the campital posing them to acts of violence. It is from the extravalue of the campital are even said to display a considerable degree of the

with the individual to whom it is administered.

states that when taken in moderation it produces in-crease of appetite and great mental cheerfulness; while in excess it causes a peculiar kind of delirium and catalepsy. The effect produced by hemp in its different forms varies, like that of opium, both in kind and in degree, with the race of men who use it, and in the matter of human flash. The Caribees are reported to have preferred sucking infants to all other food. Among the North-American Indians, the greatest luxury which a successful warrior could onjoy was the heart of his vanquished enemy. Among the Fans the heart of his vanquished enemy. Among the Fans the head is a royalty saved for the king; and this, too, is the part which fisheard Courade-Lion is said, in the old romance which bears his hame, to have partaken of, and to have declared that, "there is no flesh so convisions unto an Englishman as the head of a nouriesant unto an Englishman as the head of a Saresyne." The Feejee islanders are reported to have, in some cases, "spared the crews of English have, in some cases, "spared the crews of English and Brench ships wrecked on their coasts, as they had found, by experience, that the flesh of such persons

was tanted to an unpaissone extent by the savour of salt and tobscoo."—Energe. Brit.

CARHON, kdn'-non (Lat. canna, a reed or tube; ital. cannone, a large tube).—As an account of the prigin and progress of artillery and engines of war, from early ages to the present time, and a description the different the different that different the different the different than different the different than of the various improved weapons, and the different kinds of ordnance used in the English service, and come of the foreign armies and navies, will be found in other parts of this volume (see Armstrong Gun, Darmeren Gun, Lancaster Gun, Whitwork Gun, DEDMANCE, ARTHLERY, &c.), the present article will be devoted to a description of the method used at Woolwich and elsewhere for casting, boring, and finishing brass and iron cannon of all descriptions. It sems possible that the old method of casting guns will be superseded by the manufacture of guns out of twisted bars of wrought iron, as adopted by Sir William Armstrong; for, despite the efforts of all who wish to detract from the merits of these admirable weapons, their superiority over cast-iron guns, in many respects, has been clearly proved by the severe proofs to which they have been subjected. Nevertheless cast iron, in the improved methods of preparing it, combines very great hardness and tenacity, and is chesper than any other material. As formerly mannfactured, it was very uncertain in its character, often being far from homogeneous in texture, and, at the best, its estimated capacity of resistance being only Dest, its estumated capacity of resistance being only 20,000 lb, to the square inch, whilst the tenacity of bronze was estimated at 30,000 lb. Wrought iron pos-sesses the greatest tenacity, but is inferior in hardness. The greatest objection to its use, as is urged by the best American authorities, who manifest great par-tiality towards cast-iron ordnance, is the difficulty of constructing large masses of iron by continual re-beating and forging, as new pieces are added, without causing portions to change their texture and undergo a partial crystallization; thus weakoning the mass without any sign of this change being visible. According to some experiments made for the United States government, the greatest tenacity of cast iron was 45,870; its greatest density was 7.400. The greatest tenacity of wrought iron was 74,592; its greatest tenacity of wrought from was /25,002; 118 greatest density, 7:58. The greatest tenacity of bronze was 56,786; its greatest density, 8:953. The greatest tenacity of cast steel was 128,000; its greatest density, 7:962. It is difficult to say to what extent the improvement of these engines of war, and the defensive armour-plates of vessels and floating fortresses, will be estried. An account of the results of the experiments made in order to test the penetrating powers of the best constructed cannon when fired against targets consisting of armour-plate, teak, and inner coating, will be found under the article TARGET. In casting bronze guns, an alloy is made of nine parts of copper to one of tin; but the proportion of tin is generally increased for large guns and lessened for small ones. For iron guns, the metal obtained in Staffordelire and Monmouthshire is in no way inferior to the best Swedish iron. The principal part of the casnon used in the British service has been cast by the Carron and Low Moor companies, and other private firms; but the government have lately estab-lished a foundry at Woolwich, to avoid the necessity

by nuts and screws passing through flanges projecting from the sides. As it is built up round the model from the sides. As it is built up round the model piece by piece, the interrening space is filled with sand, mixed with a little clay and water, and rammed tightly together. The model and the mould of sand around it sogemer. The model and the mould of sand around its are made much longer than the actual length of the gun, that the whole of the gun may consist of good metal. The piece that projects from the muzzle when the cesting is finished, in consequence of this, is called the dead-head," and is cut off in a lather it contains the soum and impurities of the molten metal, which always rise to the surface when it is poured into the mould, The dead-head is also useful in supplying the shrinkage arising from cooling, when the metal contracts shout 37 of an inch in every foot. When the mould has been dried in a store, the outer casing and model are removed, and the mould itself separated in pleas, which are carefully built together in a vertical position, and imbedded in a surrounding mass of sand to receive the molten iron. The metal, selected for its toughness and hardness, is then fused in a furnace with coal, and, when liquid, is allowed to run into the mould which has been prepared to receive it. When the casting is thoroughly cooled, the dead-head is cut off, and the axis of the piece exactly found by the aid of the centering-machine. As soon as this operation has been performed, the gun is removed to another lathe, and the rings at the muzzle and breech, and those on either side of the trunnions, are carefully turned. Great nicety is required in this part of the process, for the formation of the bore is regulated by these rings. The gun is then raised by means of points resembling cones, that enter the centerings, to admit of the trunnious being turned by the action of the trunnioning machine; after which the holes that receive the tangent-scale, and the bush of copper through which the vent is bored, are cut by means of a drill. The hole in which this copper plug is screwed enters the hote in which this copper plug is acrewed enters the bore diagonally. The process of boring is next performed; the gun is placed in a boring-machine in a vertical position, and the boring effected by means of a very hard and sharp steel tool, which works at the end of a long iron bar, somewhat after the manner of a centrebit. Sometimes the gun is made to revolve, and to rise gradually as the interior is cut away by the boring-tool; and in other methods the gun is fixed, and the cutting-tool revolves. The exterior of the gun is then finished off, and it is afterwards taken to the proving-chamber. A somewhat different method is used at Woolwich for forming the models and moulds of the brass or bronze gens that are cast there. Each model is formed in three separate parts; the central part, from the case-ring to the middle of the dead-head, is made on a piece of wood less in diameter at one end than the other, that it may be readily pulled out when recasion requires it. Straw is now wound round this wooden centre, and an exterior coating of moistened sand, carth, and horse-dung put over the straw. The whole mass is made to revolve against a board out in the form of half the longitudinal section of the gun, which moulds the composition to the required shape. The model of the breech is made on a cone of iron in a similar manner, and pieces of wood are affixed in the proper places to represent the trun-nions, vent-piece, and tangent-scale. This model is then coated with a composition of sand and hair, which forms the mould for the required cannon. The model is then taken out by degrees, the wooden centre being first pulled out, and then the straw which surrounded this centre; the composition forming the exterior of the model is next removed by the action of fire, the horse-dung having the property of making the com-position light and friable; and the hollow mould, when dried, is ready for use. When the mould is put in the castog-pit, the three separate pieces in which it has been made are carefully built together and imbedded in sand, as in making the moulds already described for iron ordnance. Prior to 1750 cannon were cast hollow, of being entirely dependent on private enterprise. The solid piece and boring them afterwards was discovered first thing to be done in making a cannon is to be not be solid piece and boring them afterwards was discovered by a Swiss engineer. As the exterior cools before the interior, it is found to be of much closer grain than the part which is subsequently removed; and, on this made of iron, is set upright, and surrounded with a count, cannon made on this system were som discovered to be far superior to gues which were cast but about this date the method of casting them in a

hollow, the metal of which was more porous, and, consequently, much weaker in some parts than in others; and as it did not offer a uniform resistance to the force of the powder in every part, the piece was liable to burst at any time. The following are some of the largest and most remarkable cannon ever constructed:—1. A cannon used by Mahomet II. at the siege of Adrianople in 1463, which fired bells of stone of 600 lbs. weight. 2. A cannon at Ehrenbreitztein, on the Rhine, made in 1529: it is rather more than 18 feet long, and 18 inches in the bore. It requires a ball weighing 180 lbs. 3. The mouster cannon cast by Aurungsebe in India in 1685, named the "Lord of the Plain," which is 14 feet long, 28 inches in the bore, and will fire a ball weighing 1,600 lbs. This gun is to be seen at Bejapoor, with another iron gun of similar calibre. The mould in which it was cast is said to be in existence at Ahmednuggur at the present day. A. The huge wrought-iron gun made by Messrs. Horsfall, at Liverpool, in 1856, and presented by them to the British government. It is just 16 feet long, and weighs nearly. 22 tons. The curious brass gun at Bover Castle, known as Queen Elizabeth's pocket pistol, cast in Holland, and presented to her by the Dutch states, is a beautiful specimen of the ordnance of that period.—Ref. Endish Cyclopadia—Arts and Sciences.

"Ref. English Cyclopædia—Arts and Sciences.

Canor, kå-noo' (Fr. canot; Span. canor), a boat much used by rude nations. It is generally made by excavating the trunk or body of a tree, and then cuting or burning it into a suitable shape. Sometimes it is made of bark or skins. Some cances have decks, and are moved by sails made of rushes or skillegrass; some are large enough to earry twenty to thirty hogs-

CAMOR.

heads of sugar. They are, however, generally small in width, with barely room for two men to sit abreast: the length varies greatly. The cance is generally as open boat rowed with paddles instead of oars. As the remains of cances have been dug up in various parts of the United Kingdom, it is evident that they were much used by the ancient Britons.

Canon, Rin, is a word derived from the Greek, and used in various senses by ecclesiastical writers. Its original meaning, and that in which it is used by the apostle Paul, is rule:—"As many as walk according to this rule (Gr. canon), peace be on them and meroy."—(Gsl. vi. 16.) Hence it came to be applied in the carly Church to a law or rule, either of doctrine or discipline, enacted by persons of authority in the Church, as popes, bishops, councils. Thus we speak of the canons of the council of Nice, the canons of the council of Trent, meaning the decisions of these councils on points of doctrine or discipline submitted to them. The number of canons is very great, the collected body of them forming what is called the Canon Law (which see). The Apostolical Canons are generally believed to have been issued at a very early period, and are by some referred even to the time of the apostles themselves; whence their name. Canon was also applied to a catalogue of all the things belonging to the Church, or to a catalogue of saints acknowledged and canonized by the Church, also a book used in the service of the Church, as a collection of hymns which were to be sung on festivals. More recently it came to be applied to the divine and inspired writings; in which sense we speak of the canon of Scripture, the canonical books of the Old and New Testaments. (See Bible.) Canon is also applied to the book of laws and rules to which persons are subject who devote themselves to a religious life. These rules were frequently read over to such persons, and to them also the term canon came to be applied; thus, the Augustinian canons were those who adopted

and lived under the rule of St. Augustine. The Peachal canon is a table of the movable leasts, showing the day of Baster and the other feasts depending on it for a cycle of nineteen years. Canon is also applied to that part of the communion service or mass of the Roman Catholic church which follows immediately after the Sanotus and Hosanna, corresponding to this part of the service of the English church which begins at the prayer, "We do not presume." &c. CANON, is one who possesses a prebend, or revenue allotted for the performance of divine service in a

cathedral or collegiate church. The institution of this order is not ancient, being attributed to Chrodegangus, a bishop of Metz about the middle of the 9th century. At first they were merely inferior ecclesisatios, living in community by the cathedral, and assisting the bishop in his duties, entirely dependent on his will, and supported by the revenues of the bishopric : at first, the ported by the revenues of the manopric; at mist, they even inherited his movables. By degrees they shock off their dependence, and formed themselves into sensate bodies, of which, however, the bishops were still the recognized heads. In the 10th century there were establishments of this kind formed even in cities where establishments of this kind formed even in cities where there were no bishops, and these took the name of Congregations, or Colleges, the members being called Collegiates. The name chapter now given to these bodies was not in use till long after. In time, the canonical or collegiate life became so common that every cathedral had its chapter distinct from the sent of the clergy. They gradually relaxed in their observance of their roles, and at length they caused to live in community; yet they still formed bodies, making themselves as a necessary council of the lighton examine the rights of the rest of the elergy. making themselves as a necessary council of the bishop, assuming the rights of the rest of the elergy, and taking upon themselves the administration of a see during its vacancy, and the election of a bishop to supply it. There were even some chapters exempt from the jurisdiction of the bishop, and owning no head but their dean. After the example of cathedral chapters, collegiate ones also continued to exist as chapters, collegate ones also continued to exist as bodies after they had ceased to live in communities. Canons were of various kinds; as, cardinal osnons, who were attached, in cardinals, to a church, as a priest is to a parish; domiciliary canons, such as, not being in orders, had no right in any particular chapters; expectative canons, such as, without having any revenue or prehead, had the title and dignity of canons, a voice in the chapter, and a place in the choir till a prehend hould become vacant. Experimental canons were such as should become vacant. Foreign canons were such as did not officiate in the canonries to which they belonged, and were opposed to mansionary or residentiary canons. Lay or honorary canons were persons among the laity who, out of honour and respect, had been admitted into some chapter of canons. Tertiary canons, or such as had only a third part of the revenues of the canonicate. Regular canons were such as lived in canonicate. Regular canons were such as itsed in community, and, like religious communities, had, in process of time, added the solemn profession of vows to the practice of their rules: they were called regular to distinguish them from secular canons, who abandoned living in community, and mixed more or less with the world, but at the same time practised a religious life according to the rules of the order. The order of regular canons of St. Augustine was brought order of regular canons of St. Augustine was brought into England by Adelwald, confessor to Henry I., who erected a priory at Nostal, in Yorkshire, and obtained for them the church of Carlisle as an episcopal see, with the privilege of choosing their own bishop. They were singularly protected and encouraged by Henry I. and by Queen Mand; and it appears that under the reign of Edward I, they had fifty-three priories. This institution was carried at the time of the Referention. reign of Lowert 1, they had nily-taree profess. This institution was spared at the time of the Reformation, and it continues to the present day. Canons are sometimes called probeudaries from their being in the enjoyment of a prebend; they have stalls in the cathedral churches, which are generally called probends stalls. They are still nominally what they once actually were. the council of the bishop for the administration of the affairs of his diocese; and they constitute the chapter of the body known as the Dean and Chapter. (See DEAN.)

CANON, a vocal composition consisting of two, three, or four parts, in which he several voices begin at fixed intervals consecutively; sometimes each voice commences with the same, sometimes with different ages.

## Canon Law

Canons may be finite or infinite; the former end, like other compositions, with a undence, while in infinite examps the theme is begun again before the parts which follow are concluded. They are so constructed as to form aperpetual fague, but differ from ordinary fague; for in the latter it is sufficient for the subject to be repeated occasionally according to the laws of counterpoint, while in the former it must be strictly repeated by all the succeeding parts. In ancient music canons were rules for determining the intervals of notes. Ptolemy, rejecting the Aristoxenian method of measuring the intervals in music by the magnitude of a tone, thought that they should be distinguished according to the ratios or proportions which the sample

cording to the ratios or proportions which the sounds terminating those intervals bear to one another when considered according to their degree of acuteness or gravity, which, before Aristoxenus, was the old Pytha-gerean way. From this canon Ptolemy and his fol-lowers have been called Canonic, as those of Aris-toxenus were named Musici. Amongst the ancient Greeks this term signified what we now call a mono-

Caror Law, is a body of Roman ecclesissical law considered with respect to any intrinsic obligation, has no force or authority in this kingdom; it is no face binding in England than our English laws are binding at Rome. But, as far as this foreign law, on account of some peculiar property, has in some particular cases and in some particular courts been introduced and allowed by our laws, so far it obliges, and no further, its authority being wholly founded upon that permission and adoption. Wherever the system of canon law departs from the rules of our common and statute law, the latter take place of the former. The decrees and canons of the Church of Rome were adopted, as they then existed, by the clergy and people of England so early as the year 605. About the middle of the 12th century,—butsaid by Godolphin to have been in the year 1230, a system of laws under the influence of successive popes began to be compiled and promul-gated at different periods. This system has been generally diffused through Europe, and prevails with more or less authority in different countries under the title of the Canon law. It consists of two principal parts,—the Decrees and the Decretals. About the year 1150, that which is called the Decrees, or Decretum, having been first collected by Ivo, bishop of Carnat, Pope Eugenius, who allowed them to be read in schools and alloged for law. This is the most ancient work, as beginning from Constantine the Great, the first Christian emperor.—(Ridley's View of Civil and Ecclesiastical Law, p. 74, et eq.) The Decretals are canonical epistles written by the popes, or popes and cardinals, for determining some matter of controversy. These were compiled by Raymundus Barcinius, chaplain to Greatow IX and multipled at his command about the Gregory IX., and published at his command about the year 1231, to which Boniface VIII. added a sixth book in 1298. The Clementine Constitutions, which appear to be intended as a continuation of the Decretals, were be intended as a continuation of the Decretals, were sompiled by Clement V., and published by his successor, John XXI., at Avignon, in 1317, who afterwards collected some further constitutions, which were published about the year 1340.—(Ridley, i.b.) A seventhese of Decretals and a book of Institutes were added by Gregory XII., under whose sanction the Corpus wars Convenics, containing all the several parts, was published in 1580. The Decrees appear to set out the origin of the canon law, and the rights, dignities, and degrees of ecclesiastical respons, with their manner and degrees of ecclesisatical persons, with their manner of election, ordination, &c. The Decretals contain the law to be used in the ecclesiastical courts. body of esnonical law of foreign origin must be added the constitutions passed in this country by the pope's legaces. Otho and Othobon, and the prelates of England, assembled in national councils in 1237 and 1269, and assembled in national councils in 1237 and 1269, and confirmed by the queen, they were, by royal authority, also the constitutions framed in provincial synods under the authority of successive archivishops of Canterbury and tensmitted to the two provinces of Canterbury and the sample of Canterbury and the confirmed by the queen, they were, by royal authority, tensmitted to the two provinces of Canterbury and the two provinces of Canterbury and tensmitted to the two provinces of Canterbury an

# Canons of the Church of England

sentence, endeavour to enforce obedience to such part of the canon law as was inconsistent with, or opposed to, the common law, the courts at common law, upon complaints made, would grant prohibition. The authority vested in the Church of England of making canons ruy rested in the Church of England of making-canons was ascertained by the statute of 25 Hen. VIII. 8, 19, commonly called the Act of the Clergy's Submission, by which they acknowledged that the convocation had always been assembled by the king's writ; so that, although the power of making canons resided in the clergy met in convention. clergy met in convocation, their force was derived from the authority of the king's assenting to and confirming them. The old canons continued in full force till the reign of James I., when the clergy, being the reign of James I., when the deergy, seeing assembled in convocation, the king gave them leave.to treat and consult upon canons, which they did, and presented them to the king, who gave them the royal assent. These were a collection out of the several preceding canons and injunctions. Some of these canons are now obsolete. In the reign of Charles I. several canons were passed by the clergy in convocation. A most elaborate history of the canon law will be found in the historical introduction to Ayliffe's Parergon.

Canoss, Book or, in Scottish Eccl. Hist., was a code of canons or laws prepared by the Scottish pre-lates, and confirmed under the great seal by letters-patent bearing date May 23, 1635. These canons were Scotland, and enjoined adherence to the liturgy, which had not yet been published or even prepared. They decreed excommunication against all who should deny the king's supremacy in ecclesiastical matters, or that should dare to say that the liturgy (unpublished) contained anything contrary to the Scriptures. No general assembly should be called but by the king; no ecclesions siastical business should be discussed, except in the prelatic courts; no private meetings should be held by ministers for expounding the Scriptures; and on no occasion, in public, should a minister engage in extempore prayer. Great indignation was felt all over Scotland when the character of these canons came to be known; and though it did not then break out into positive violence, it added greatly to that deep undercurrent of feeling which soon afterwards broke out with such violence.

CANONS OF THE CHURCH OF ENGLAND. kan'-ons. Bre certain laws and constitutions made for the government of the Church, and which have received the assent and confirmation of the kings of England. Even when the papal power was most dominant in England, from the time of William 1. to the Reformation, the Church had no power to enforce any canons or constitutions which had not received the royal assent. The canons in force at the time in England were all collected, explained, and systematized by Lyndwood, dean of the Arches in the reign of Henry VI. It was intended to reform there canons soon after the Reformation, and Cranmer and some other commissioners were appointed for that purpose by Henry VIII, and Edward VI. The work was completed; but the king dying before it was confirmed, it still remains unconfirmed. The book is called "Reformatio Legum Ecclesiasticarum ex authoritate Regis Henrici VIII. inchoata, et per Eduardum VI. These canons are still binding, and are acted provecta." upon in the ecclesiastical courts, except where they are superseded by subsequent canons or by acts of parliament. Another book of articles or canous was made at a provincial synod in London, April 3, 1571, by Parker, archibishop of Canterbury, and the rest of the bishops; but it is not said to have been confirmed by royal authority. In the 27 Eliz, certain canons were agreed to by the archbishop and bishops at a provincial synod at London, Nov. 24, 1534, and after-wards confirmed by royal authority. Other canons and constitutions were treated of by a provincial synod and constitutions were treated of by a provincial synoic of Canterbury, and being afterwards approved of and confirmed by the queen, they were, by royal authority, transmitted to the two provinces of Canterbury and York, and published for the due observance of them. In 1603 a synoic assembled at London, under the archibishop of Canterbury, in terms of a writ issued by

Canonica

Canopus

convenient for the honour and service of God, the good and quiet of the Church, and the better government thereof, to be from time to time observed, per-formed, fulfilled, and kept by the whole clargy. These canons are 141 in number, and are for the most part a digest of old canons, with some new ones added. They treat-1. Of the Church of England; 2. of divine ser vice and administration of the sacraments; 3. of mininters, their ordination, function, and charge; 4. schoolmasters; 5. things appertaining to churches; 6. churchwardens and side-men; 7. parish clerks; 8. ecclesiastical courts; 9. judges ecclesiastical and their surrogates; 10. proctors; 11. registrars and apparitors; 12. authority of synods; forming the basis of the ecolesinstical law as bearing upon the clergy, but not binding upon the laity, except in so far as they are declaratory of the ancient canon law. In 1640 the convocation then assembled passed a body of canons, which were ratified by the king under the great seal the same year; but being of a very arbitrary nature, an attempt was made at the time to set them aside, on the plea that the convocation could not lawfully continue its session after the dissolution of parliament. The opinion of the judges at the time was unanimously in favour of the legality of the proceedings; but they were unanimously rejected by the Commons, and, by an act passed in the 13th year of Charles II., they were abrogated.

—Ref. Hook's Charch Dictionary.

CANONICE, or CANONICES, kin-on'.i-se, was a name given to ecolesiastical virgins, from their being

enrolled in a canon or catalogue of ecclesiastics. They differed from monastic virgins in not being confined to a choister, but in living ordinarily in the houses of their

parents.

CANONICAL, kan-on'-e-kal, of or belonging to the cauous of the church. Canonical hours are certain stated times of the day assigned to the offices of prayer and devotion, "that all Christians throughout the world might at the same time join together to glorify They are observed principally among Roman cros. They are conserved principally among Roman Catholics, and are prime, torce, sext, and nones—the first, third, sixth, and uinth hours of the day; i.e. at six, nine, twelve, and three o'clock; vespers in the evening, at six; complin, as completing the services of the day; and matins and laude shortly after midnight. In England the canonical hours are from eight to twelve o'clock, before or after which marriage cannot be legally performed in any parish church. Canonical letters, in the ancient church, were testimonials of the orthodox faith sent by the bishops and clergy to each other in order to keep up the Catholic communion, and to distinguish Christians from heretics. Canonical life, the method or rule of living prescribed by the ancient clergy who lived in community. Cononical obedience is that submission which, by the ecclesiastical laws, the inferior clergy are bound to pay to their bishops, and religious persons to their superiors. In the Church of England every clergyman takes an oath of canonical obedience to his hishop when he is instituted to a benefice or licensed to a cure. Canonical punishments are those which the Church has in its power to inflict, sa in Roman Catholic countries excommunication penunce, and the like. Canonical sins, in the ancient church, were such as were deemed capital or mortal;

as idolatry, nurder, hereay.

Canonici, kim-on-i-si, a term applied in early times to the clargy, from their names being carolled in a canon or catalogue of some church.

CANONICS, or CANONICA, kin-on'-iks, the name applied by Epicurus to his system of logic, as consisting only of a few rules or canons. He rejected the dis-lection of the Stoics, as full of vain subtilities and deceits, and fitted rather for parade and disputation than for directing the understanding in the pursuit and attain-ment of truth. Canonics treated of the means by which knowledge, both physical and ethical, was obtained, and of the conditions or criteria of truth. These conand of the conditions of ordered of truth. These conditions, seconding to him, were sensations, ideas or imaginations, and affections. From these three sorts of consciousness we get all our knowledge, which is either physical or moral: the former perceived by the sense, the latter by the understanding. In reality his causaies correspond very much to what is now termedpsychology.

Esmonicum, kän-on'-e-kum, in a ganeral sense, de-

notes a tax or tribute. It is more particularly in the Greek church for a fee paid by the clean bishops, archbishops, and metropolitans, for degree and promotions. It is also applied to the first am paid by the Greek laity to their bishops or prients, a which is regulated according to the number of hem or fires in a place.

CANONIST, Ein'on-ist, is a person skilled in, or was professes, the study and practice of the canon law Canonists and civilians are usually combined in the aame persons; and hence the title of juris stringer. doctor, or legum doctor, which is usually expressed by J.U.D. or LL.D.

Canonization, kin-on-i-zai'-shun, in the Roman Catholic church, is a ceremony by which a deceased person is enrolled in the canon or catalogue of the Canonization was not known in the Christian church till about the middle of the 10th century, and it seems to have been borrowed from the custom among the Greeks and Romans of deifying the more distinguished of their great men and haroes. It pro-bably took its rise in the practice of the Church invoking the aid of early martyrs. The hishops at first decides who were entitled to this honour, and afterwards who was at first a mere local decision came to be converted into an imposing ceremony, and the power of conferring this honour was appropriated by the population Alexander III., in 1170, pronounced it an exclusive privilege of the papal chair. At first none but marries were admitted into the category of saints; but afterwards men of distinguished piety were admitted to this honour; and in later times the pope assumed the right of admitting also such kings and potentates as had greatly favoured his temporal interests. Now, steps can be taken towards canonization until fifty ye after the person's death; but formerly there were no restrictions in this respect, and the honour was frequently obtained through family interest or the intrigues of friends. A few pretended miracles at the tomb were sufficient to give one a claim to have his name inscribed among the saints. Since the time of Benedict XIV., an official, known as l'ovvocato del Diavolo (the Devil's advocate) is employed, whose business it is to sift the evidence brought forward, and to endeavour to oppose the admission of the candid The first step towards canonization is beatification (which see). After beatification has been obtained, new suit is necessary in order to obtain the canonica-tion of the same individual. For that purpose, the pope holds four consistories. In the first he causes the petition of those who request the canonization to be examined by three auditors of the rota, and directs the cardinals to revise all the necessary instruments; in the second the cardinals report the matter to the in the second the cardinals report the matter to the ope; in the third, which is in public, the cardinals pay their adoration to the pope, and the Devil's advecate makes his appearance, raising doubts as to the genuineness of the miracles, and exposing any want of formality in the procedure. On the other hand, another advocate makes a pompons oration in praise of the candidate, and expaniates at great length on the miracles which he is said to have wrought. In the fourth consistory, the pope, having summoned together the cardinals and prelates, orders the report concerning the deceased to be read, and then takes their votes whether he is to be canonized or not. On the day of the canonization the church of St. Peter is hung with rich tapeatry and most brilliantly illuminated, while the pope and all the cardinals officiate in white. The ceremony, which is very magnificent, and presided over by the pops in person, is very expensive, and

CANONEY, or CANONICATE, kint on re, is the name of the office filled by a canon. A precend may exist without a canonicate; but the canonicate inseparable from the precend. It is the canonicate that gives the right of suffrage and other privileges to the canon, and

not the prebend.

Canopus, kd-no'-pus, a very bright star of the first magnitude in Argo, a constellation of the southern hemisphere. The origin of the name is uncertain; but it was probably derived from the ancient Egyptina city. Canopus, or Canobus, which was situated on one the mouths of the Nile called the Canopic mouth, show three miles distant from the modern Aboukir.

Canopy

Canticles

CAROPT, kān'-o-pe (Gr. konopeion, from konops, a gnat), word meaning in its original sense a covering similar to the mosquito curtains of India, to protect the sleeper from those insects. Subsequently the term canopy was applied to any ornamental covering above the head, for the purpose of distinction, honour, or adornment. for the purpose of distinction, nonour, or subminimization this sense the word is synonymous with the term baldachin. (See Baldachin.) In Arch., it is applied to the coverings that project from the surface of the wall above the heads of statues placed in niches and to the directories over windows. over altar-tombs, and to the dripstones over windows when elaborately carved. Magnificent specimens of canopies are to be found over the tombs of some of our kings, and over the bishop's throne in many of our ca-thedrals. The canopy is a peculiar feature of Gothic architecture, belonging principally to the Decorated English and Perpendicular English styles. The canopies that are found over altar-tombs are generally formed by a flat roof supported on pillars at the sides, with a series of beautifully-carved arches running from pillar to pillar in the front. Those formed in recesses are often groined and adorned with pendants. Some canopies, particularly those erected over bishops' tiers most elaborately chiselled, and terminate in a spire adorned with crockets and a finial.—Ref. Parker's Glossary of Architecture.

CANT, kant, is a term to which various derivations

have been assigned. By some it is derived from the Latin cantus, sung; by others from quaint; and by others from Andrew Cant, a rather prominent Scottish divine of the 17th century. It denotes a quaint affected manner of speaking or writing, or the speakamended manner of speaking or writing, or the speak-ing in a whining, affected tone of voice. It is more particularly applied to a peculiar manner of preach-ing, praying, or begging. It also denotes the fre-quent use of phrases not well understood; or the use of terms of a particular profession or class of indi-viduals. So, givey cut. It signifies also the selling or viduals; as, gipsy cant. It signifies also the selling or bidding at an auction.

CARTABRI, kan-tai'-bre, in Ancient Hist., the name of a rude people of Spain, inhabiting the mountainous districts between Palencia, la Montaña, and Asturias, to the shores of the Bay of Biscav, which, after them, was called the Cantabrian Sea. They are described as resembling the Scythians and Thracians; and by their bravery they maintained a six years' contest with the Romans, begun by Augustus and concluded by Agrippa (B.C. 25-19). A portion of the people still remains: (B.C. 25—19). A portion of the people still remained unsubdued in their native fustnesses, and from these the Basques of the present day are believed to have

CANTATA, kan-ta'-ta" (Ital., from cantare, to sing), in Mus., an elegant species of vocal composition, of which there are several kinds, supposed by some to have been invented by Barbara Strozza, a Venetian lady, about the middle of the 17th century, while others attribute its invention to Giacomo Carissimi, pontifical Leonaida of an intermixture of maestro di capella. It consists of an intermixture of air and recitative, and was at one time extended to such a length as to form a sort of small opera, but is much a length as to form a sort of small opera, but is now, however, ordinarily written for only one voice with a therough base, though sometimes for several, accompanied by one or more instruments. In Italy, companied of great length, accompanied by a numerous band, are usually performed on great occasions of festivity, such as the reconciliation of princes after. a long disunion, or the arrival of great personages in the capital of a state. But these differed essentially from what is usually understood by a cantata, or mosologue, consisting of short recitatives and two or three airs at most, as they are occasionally poems in which several singers are employed. According to Du Cange, the word cantata was used in the Church as early as the year 1314 to express what is at present understood by anthem, with which word it is still synonymous in Germany, cantatas being chiefly confined, in the

bidden in 1847. The canteens are rented from govern ninden in 1847. The cantesis are rented from government: it is to be hoped that soldiers' club-houses will soon be substituted for them. The term canteen is also applied to a chest in which officers carry plate, spirit-cases, teg, sugar, and other requisites; and to a small wooden vessel, or cask, made of oak, slung by a small wooden vessel, or cask, slun strap over a soldier's shoulder, and used to carry water or any other liquor when on the march. They hold about three pints. They are painted blue, and marked with the number of the regiment and letter of the company to which the owner belongs

company to which the owner belongs.

Canter, kin'-ter, the movement of a horse going at a moderate gullop, when the fore feet are raised nearly together, with a leap or spring. The name is derived from the easy pace and gentle gullop with which the pilgrims were in the habit of traversing the roads to

phyrims were in the name of traversing the roads to the shrine at Canterbury. CANTERBADIN, kān-thā'-rā-din, the crystalline blis-tering principle contained in the Cantharis vesicatoria, or Spanish blister-fly, first obtained by Robiguet. procure it the flies are digested in alcohol. The alcoholic solution is afterwards evaporated to dryness, and washed with cold ether, which dissolves out the cantharadin. When pure, it is insoluble in water, but very soluble in boiling alcohol. Lard containing one five-hundredth of cantharadin will produce a very powerful bilistering offest when you'ld to the hundredth. blistering effect when applied to the human skin.

CANTHABIDE, kan-thar'-e-de (Gr. kuntharos, a beetle), CARTHARDE, Kent-tuar -e-de (Ur. Kaunauros, s Decky), the name given to a fam. of coleopterous insects, very numerous, much variegated in colours, of moderate size, and generally living on vegetable substances, They are distinguished by the head being dilated behind the eyes, and then suddenly narrowed into a short neck. When slarmed, they counterfeit death; and some varieties at the same time emit a thick yellowish fluid, with a disagrecable smell, from the arti-culatories of the legs, &c. Many species are employed externally in medicine to produce blisters, as they possess strong vesicating powers. They are also used internally as a powerful stimulant. Many species of the gen. Cantharis which possess this property are natives of Europe, India, and America. The Cantharis vesicatoria is the common blister-fly of the shops. (See BLISTER-FLY.) The striped cantharis is a native of North America, where it is called the Potato-fly. The gen. Mylater contains several species, which have properties to those possessed by the Cantharis; and the Markoe has also various species which have all the properties of the hister-fly.

Canticus, kin'te-ile (Heb., Song of songs), a name frequently given to the Song of Solomon, the 22nd in order of the books of the Old Testament. There is no other inspired book concerning which so much diversity of opinion has been entertained. In modern times many attempts have been made to deny the canonicity of this book, not so much on historical or critical grounds, but from the subject of the book itself. The ancient Jews, without exception, regarded it as a sacred book, and it is cited as of divine authority from the earliest times of the Christian church. As to the authorship of the book, some have maintained that it is not the work of one, but of several authors, or a collection of early songs made by some later hand; others that it belongs to an age much later than that of Solo-mon. The book itself professes to be the work of

Solomon, and the unanimous testimony of tradition is in support of this view. There are also in it frequent allusions to the time and circumstances of Solomon, a time when the kingdom was in peace and power, while the profusion of its imagery, gathered from foreign as well as domestic scenes, shows it to have been written at a time when the Jews had extensive intercourse with neighbouring nations, and singularly confirms the view of its being Solomon's, who had a remarkable liking for foreign grandeur. The continuity of the subject and sameness of the style, mark it as the work of one author. The interpretation of the book itself is a sub-In termany, catters being chiefly domined, in the author. The interpretation of the book itself is a subject which has given rise to much discussion. The book is an amatory poem. The assumption of a love-scaling or place within the barracks where the soldier may burdiase beer and spirits. It is under the control of the officer in command, who can regulate the analysis and see that the cantineer supplies liquor of a practises no imposition on his customers. The sale of spirits at these places was for-Christ for his church. Luther assumed it as a political

428

# Cantilever

sliegory referring to the happy consequences of Solomon's reign; and more recently it has been held to be a prophetical description of the Christian church. The German rationalists of the last century maintained the literal interpretation of this book, and this has been the prevailing opinion in that country since that time; but some of the recent expositors, as Hengstenberg, haverecurred to the allegorical interpretation. Those who interpret it literally regard it as celebrating the love of Solomon for an Egyptian princess, or for a daughter of Israel; and some consider it as setting forth the beauty of conjugal fidelity, and commending monogamy. Some orities divide the book into twelve distinct poems or idyls; others into plots of seven days, commensurate with the period of a marriage feast; while others regard it as a drama of four or six acts. According to Dr. Jahu, the book divides itself into distinct songs, as follows:—1. An innocent country maiden makes an undisguised profession of her attach-ment, and her lover replies to it with equal protestation of affection (i.2—ii.7). 2. A maiden sings of her lover, who is seeking her everywhere, and she also confesses her warm affection (ii. 8-iii. 5). 3. A maiden in a litter surrounded by Solomon's soldiers, is brought to the harem of the king. The lover prefers far before all the royal beauties his own beloved, in whose society he declares that he is happier than the king himself (iii. 6-v. 1). 4. A maiden beloved sings of her lover. He had come to her door at night, and had fied away before she opened it. She seeks him, is beaten by the watch, and stripped of her veil. She describes the beauty of her lover, who at length answers, celebrating her loveliness with a contemptuous glance at the multitude of the king's wives (v. 2—vi. 9). 5. Shalamith recounts in few words the allurements of the courtiers whom she had met with unexpectedly in the garden, and her rejection of them, and celebrates her affection for her lover (vi. 10-viii. 3). 6. Protestations and praises of constant affection (viii, 4-7). 7. A discourse between two brothers about guarding and giving away their sister in marriage, who replies with scorn that she would be her own guardian (viii. 8-12). 8. A fragment, A lover wishes to hear his beloved. She replies by persuading him to fly; perhaps, because her parents or relations were near, who, in the East, never allow such meetings (viii. 13, 14).—(Introduction to the Old Testament.) Some of these divisions are sufficiently fanciful, as indeed is the case with all the attempts that have been made of the same kind. The truth seems to be that the poem is destitute of any plan, and that it aims sin ply at placing the love of the king and his bride in a variety of aspects. With all the change of scenery there is no change of the relations subsisting between the parties who appear in each successive scene. The difference of manners between successive scene. The difference of manners between the East and West is to be kept in view in considering this song, which is also far more delicate in the Hebrew than in any Europeau dress. Allegory is even to this day a favourite mode of expression in the East, and the veiling of spiritual fervour and enjoyment under the figure of love is common to all eastern nations. Many good persons, however, in their attempts to reconcile the literal with the spiritual sense of this book, have injudiciously carried their attempts too far, and have been led beyond the boundaries which a reverence for the sacred Scriptures should ever prescribe. The Jews did not allow their youth to read this book before the age of thirty.

CANTILEVER, kän-ti-le'-ver (probably fr. Lat. cauterii

labrum, the lip of a rafter), a projection from the face of a wall, used to support baloonies and ornamental

CANTILEVEB.

cornices, answering the same purpose as a bracket, but widely differing from it in form. It is often used synony. mously with the term bracket; but, strictly

should be confined to long pieces of wood, iron, or stone, projecting for some distance from the wall, but comparatively narrow in width and depth. The prolevers. A good pictorial illustration of the term may be seen in the engraving appended to the article Bal. indeed, derived from the causes of change of the

# Canzone

The word is also spelt cantalever, cantaliver, and cantliver.

CANTO, kan to (Ital. canto, a song), a part or division of a poem, answering to book in prose.

CANTON, kan ton' (Fr. conton; Ger. kante, a corner).

UNITON, Kanton [Fr. conton; ver. kunter, a volume, a in Her., one of the nine honourable charges or ordinaries, occupying a third part of the chief, or exactly one-ninth part of the field. It is square in form, and is borne on the dexter or sinister side of the shield.

Canton (Fr. canton, a district), a term employed in Geog. to denote a portion of territory forming a sepa-rate state or government. Switzerland is divided into cantons. The arrondiscements in France are subdivided into cantons, of which there are 2,971; and these are again subdivided into communes.

CANTON'S PHOSPHORUS.—The protosulphide of cal-cium, when newly made, is very phosphorescent. This property was discovered by Canton, who first prepared this substance by calcining oystershells and mixing the whitest pieces with one-third their weight of flowers of sulphur, and recalcining them in a crucible with a luted cover. When heated for an hour, the whitest pieces were selected and preserved in well-stoppered bottles.

CANTONMENTS, kan-ton'-ments (Fr. cantonnement). In Mil., troops are said to go into cantonments when, either on account of the inclement state of the weather, difficulty of obtaining supplies, an armistice, temporary suspension of operations in the field, or other causes, the general commanding determines to quarter his troops in the towns and villages of any particular district, instead of putting them under canvas. A careful examination of the capabilities and natural position of the district is first made by the quartermaster-general and officers of engineers, and the men are then billeted in the villages and farmhouses, but kept together as closely as persible, in order to resume active opera-tions whenever it may be required. Headquarters and a main guard are established in some central and commanding position, pickets of cavalry and advanced guards are posted at outlying points to watch every approach to the neighbourhood in which the troops are placed, and everything is done that is necessary to secure the position in event of the enemy making a sudden and unexpected advance. The term cantonments is applied in India to barracks built near any large town or city for the reception of troops. They correspond very nearly to our own barracks and permanent camps, with this particular difference, that the quarters of the various troops are not contiguous, but are spread over an area of considerable extent. The are generally situated at some little distance from any town to which they are attached, and comprise quarters for European and native troops of all arms of the serthe curopean and native roots of an arms of the service,—cavalry, infantry, and artillery, with separate burgalows for the officers. Parade-grounds, magazines, mess-rooms, offices, and bazaars, are attached. The cantonments near Delhi are pleasantly situated on a rising ground to the north of the city, about two miles from the Cashmere gate. The cantonments, or lines, at Meerut will ever be remembered in Anglo-Indian bistory as the root in which the absorber Indian history as the spot in which the slaughter of European officers and their families, that so signally marked the first act of the sanguinary drama of the Indian revolt, was commenced by the infuriated mutineers.

CANTRED, OF CANTRETH, kän'-tred (Brit. cant, a hundred, and tref, a town or village), is used in Wales in the same sense as a hundred in England, denoting a certain division of a county.

Canvas, kim'-ris (Fr. canevas), a coarse material used for the sails of vessels and for the foundation of painted cloth for floors. The term is also applied to a light material woven with the warp and woof at intervals, so as to leave square interstices between them, and used by ladies for tapestry and Berlin-wool work. And used by ladies for tapesty and bernit respectively. Painter's canvas, on the contrary, is a material of very close texture, called "ticking." It is generally purchased stretched on frames of various sizes, and primed with a light neutral grey or drab tint ready for

Provençals; but the Italians were the first to give it a definite form. It received its classic stamp principally from Dante and Petrarch. With them the cauzone was any considerable lyric poem divided, like the Greek strophic ode, into stangas exactly corresponding to one another in number of lines, metre, and position of rhymes; the last stanza being commonly shorter than the others, and usually consisting of a valedictory ad-dress by the poot himself to the poem. After Petrarch the Italiana began to deviate from the strict form of the causone, among whom were Tasso and Chiabrera. CANSONETTA (Ital., dim. of cansone), is an abridged

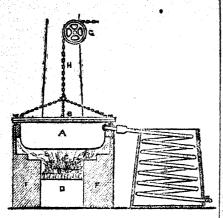

ansone written in short lines and verses.

CLOUTCHOUC, INDIA-RUBBER, or GUM-BLASTIC, kit-chook (its Indian name).—Caoutchoucisthe solidified milky juice of certain tropical plants, the largest supply being obtained from the Ficus clastica, a tree belonging to the ord. Moracea, found in Assam; from other speto the ord, Moracea, found in Assam; from other speiss of Fiess growing in Java and America; from the Siphonia elastica, a native of Guinna and Brazil; and from the Uracela elastica, a climbing plant found in the islands of the Indian archipelago. Many other plants yield caoutchouc in small quantities; such as the common fig (Fieux carica), the spurge, the dandelion, and the calandine. The milky juice of these plants consists of the caoutchouc mechanically suspended in the form of small globules in a thin aqueous fluid charged with soluble vegetable matter. In this respect it bears great analogy to cows' milk (see Milk), which is also thin aqueous fluid holding insoluble globules in mechanical suspension. The analogy is further borne out by its behaviour when left to itself. Preserved in close vessels, it separates into two portions, the more solid part, the caoutchoue, rising to the top, and formsolid part, the caoutenous, raing to the top, and forming a thick cream upon the surface. Prepared in this way it contains many impurities. The likeness borne by this milky juice to animal milk has caused it to become an article of food in several countries, and the juice of the cow-tree, or hya-hya of tropical America, the commend in large quantities by the natives of the is consumed in large quantities by the natives of the district in which it grows. The caoutehous of commerce occurs in the form of large shapeless masses collected at the foot of the tree which has been cut. or in rude cylinders formed in clay moulds. It is also imported in the shape of bottles, figures of animals, imitations of the human foot, &c. These are made by imitations of the human foot, &c. dipping a rade clay mould repeatedly into the juice and allowing the caoutchout to solidily between each operation, the clay being broken and extracted when a sufficient thickness has been obtained. Such is the raw India-rubber of commerce, the properties of which are too well known to need description. When first introduced into this country, about a century ago, its only use was to offace marks made by lead penois. Its electricity and imperviousness to moisture were well isows, but the impossibility of procuring it in large mentioned. In 1819 Mr. T. Hancock commenced experiments on its solubility in different fluids. - His est experiments were unsuccessful, and he directed his ingenuity to a process for outting the bottle-shaped masses into thin pieces, and applied them to the making of elastic bands for gloves, waistbands, garters, stays, patterns, clogs, &c. In the process of manufacture he accumulated an immense quantity of waste pieces, which he turned to use by taking advantage of the property that caoutchouc possesses of uniting when mbined into a mass by means of a machine called a marticator, which consisted of a spiked rollor working inside a hollow spiked cylinder. At first, only two ounces at a time could be masticated; but by larging his machinery he worked up large masses which could be afterwards out into sheets and blocks. He further discovered that these sheets sould be dissolved in oil of turpentine. an important discovery, leading to the invention of waterproof cloth by Mr. Charles Macintosh. The method by which this was effected consisted in cementing together two surfaces of catton-work cloth ans of the esoutchouc solution. This formed a given the name of Macintosh. Mr. Hancock continued milding experiments on the liquid caoutchous imported from Peru, but found be could use more successfully

the solution above named. The uses to which the solution was applied are so numerous that it would be impossible to mention the whole of them. In 1831 a method of making clustic fabrics, having threads of enoutchouc in the warp or west, was introduced. The manner in which the threads were formed is ingenious. A round flat disk of caoutchous was made by cutting a bottle into halves and subjecting them to pressure; the disks were then cut into ribbons by a knife revolving spirally, the ribbons being afterwards sliced into square threads by another machine containing a series of cut-The shreds thus prepared were stretched to their full extent while warm, and, being kept in a state of tension until they were cool, it was found that they did not spring back to their original length until once more heated. The stretched thread was covered with cotton, and used as the warp of the labric into which they were made. When woven, the labric was beaten, which caused the caoutchout to relax, reassuming its clustic condition. Caoutehoue continued to rece numerous applications in manufactures, civil and mechancal engineering, domestic appliances, and surgical instruments, until 1842, when the most remarkable discovery in relation to this material was made by Mr. Goodyear, an American inventor. In this year an agent of this gentleman brought to England a few specimens of caoutchouc which had been treated so as to lose its three great detects of hardening by cold, becoming sticky and relaxing by best, and dissolving in oil and grease. The new material also possessed greater toughness and almost perfect elasticity. The inventor wished to sell his invention; but as the process was not communicated, English manufacturers declined to treat. The indefatigable Mr. Hancock at once set to work to produce a similar material, and after expending much time and labour in investigating the matter, he discovered a means of combining caoutchour with sulphur, producing the substance known as rulcanized India-rubber. Since that period various methods have been devised for its manufacture, by knowding certain proportions of caoutchoug and sulphur in a masticator; by dissolving caoutchoug in sulphurized oil of turpentine, which is afterwards allowed to evaporate; by dipping the rubber in a solution of chloride of sulphur in bisulphide of carbon; and several other methods more or less important. The perfect elasticity of the new material, the case with which it could be moulded into various shapes, the properties of resisting heat, cold, and solvents, soon remored its use uni-versal. Its applications to engineering purposes were most important. It soon superseded the use of metal springs for the buffers of locomotives. It replaced leather for valves and washers, and waterproof overstones began to be manufactured under Goodyear's patent by millions. Since 1842 the trade in Indiarubber articles has steadily increased, the imports having quadrupled in ten years. By combining coouchouc with sulphur at an elevated temperature, a hard, light, intensely black substance called ebonite, or valcanite, has been formed; for a description of which consult articles Ebonife and Vulcanite. (See also settles Kampulloon and Lindlews). Mr. William Hynry Barnard hus taken out a patent for a chemical solvent not hitherto used in the arts, which promises to become most serviceable, from the fact of its posseesing two very extraordinary characteristics, viz., that when in a liquid condition it has less apecific gravity than any other substance yet known to the chemist, being considerably lighter than sulphuric ether; whilst in a state of vapour it is heavier than the most ponderous of the gases. When mixed with alcohol, it acts as a solvent of copal and all the resins, at the ordinary temperature of the atmosphere. Caout choncine, the name given to this new material, peculiarly useful for making varnishes in general. It also mixes readily with oils, and will be found a valu-able and cheap menstruum for liquetying oil-paints: and, without in the slightest degree affecting the most delicate colours, will, from its ready evaporation, cause the paint to dry instantly."—(Ure's Diet., its edition.) Mr. Barnard, in the specification of his patent, thus describes the mode of preparing excus-choucine:—"I take a mass of indis-rubber as insorted, and having cut it into small lumps, containing about two ouble inches each, I throw these lumps into

# Caoutchouc

a cast-from still with a worm attached. A is the still, B the cover, C the fire-place, D the seb-pit, E the worm-tub and worm, F the brickwork of the still, G a roller and carriage, H the chain. I then apply heat

to the still in the usual manner, which heat is increased until the thermometer ranges at 600° Fahrenheit, or thereabouts. And, as the thermometer ranges progressively upwards to 000° Fahrenheit, a dark-coloured oil or liquid is distilled over, which I claim as my said invention, such liquid being a solvent of caoutchouc and other resipous and clearinous substances. When the thermometer reaches 600°, or thereabouts, nothing is left in the still but dirt and charcoal. I have found the operation of distillation to be facilitated by the addition of a portion of this oil, either previous or subsequent to rectification, in the proportion of one-third of oil to two-thirds of escutchout. I afterwards subject the dark-coloured liquid thus distilled to the ordinary process of rectification, and thereby obtain fluids varying in specific gravity, of which the lightest hitherto has not been under 670, taking distilled water at 1000, which fluid I also claim as my invention. At each rectification the colour of the liquid becomes more bright and transparent, until, at the specific gravity of 0080, or thereabouts, it is colour-less and highly volatile. In the process of rectifica-tion (for the purpose of obtaining a larger product of the oil colourless) I put about one-third of water in the still. In each and every state the liquid is a solvent of caoutehoue and several resinous and oleaginous substances, and also of other substances, such gibous substances, and also of other same as so, such as copal in combination with very strong alcohol. Having experienced much difficulty in removing the dirt which adheres to the bottom of the still, I throw into the still lead and tin in a state of alloy (commonly called solder) to the depth of sbout half an inch, and as this becomes fused, the dirt which lies on the surface of it is more easily removed. Objections having been made to the smell of this liquid, I have found such smell removed by mixing and shaking up the liquid with nitro-muriatic scid or chlorine, in the proportion of a quarter of a pint of the acid (of the usual commercial strength) to a gallon of the liquid. Obemically considered, pure caoutchone is a carbide of hydrogen, or hydro-carbon, C.H., possessing a specific gravity of 0.02 to 0.97 (Faraday). It is prepared by dissolving the commercial material in chloroform, precipitating with alcohol, and deying at a temperature of 70° to 80° Fah. As it is found in commerce, it is a dark-brown meterial, soft and elastic called solder) to the depth of sbout half an inch, and commerce, it is a dark-brown material, selt and elastic at ordinary temperatures, hardening temporarily at about 40° Fah., and melling at 250° into a liquid having the consistency of tar, which coes not soon resolidity. It is insoluble in water and alcohol, but dissolves more or less readly in chloroform, washed ether, bisulphide of carbon, coal-tar, naphtha, benzole, and oil of turpentine. Nitric acid, sulphuric acid, and

431

# Caoutohous

the alkalis, attack it but slowly. According to Payer, caoutchouc consists of two portions, one of which is soluble in the liquids above mentioned, while the other only swells and softens under their influence. Caoutchouc discovers in the fixed oils, but less its shatic properties thereby. Distilled in close results, excutchouc furnishes a mixture of several hydrocarbons, which possesses powerfully solvent properties. By careful distillation at different temperatures, this mixture is separated into liquids of different densities and boiling-points. One of these is remarkable for its low specific gravity, 630 at 25° Fah., and for boiling at a candokine to one of these hydrocarbons having a specific gravity of 842 and a boiling-point at 340°. It resembles oil of turpentine in most of its properties. Among the less volatile portions, Bouchstrat found a yellow oily hydrocarbon, which he named keedens. He also obtained tetrylene (which see); coortchesse, a liquid of specific gravity 650, which boiled at 58°, and yielded crystalline plates at 14°; and a third compound, which he considered to be expion (which see). Caoutchous, in its unvulcanized state, is most useful in the laboratory, for connecting the tubes of apparatus. Its power of resisting re-agents, and its property of cohering to form a tight joint when newly out, render it a desideratum in the modern laboratory. In its permanently-melted condition, it forms a valuable late for pneumatic apparatus. Stoppers and stopcocks lubricated with it remain movable, yet perfectly air tight. Vulcanised, it serves for gas-bags and tubes, and for many other purposes. It must, however, be used with great care, which it passes. We borrow from Mr. Buncock's work the following places:—

CAOUTCHOUG MINERAL, on clastic bituminous mineral, resembling caoutchouc in its physical properties. A few specimens of this substance have been found in a lead-mine in Derbyshire, in a coal-mine at Moxbrelais, and in bituminous limestone at Woodbury, in Connecticut.

CAR, kap (Lat. caput, the head), is the garment that covers the head. Caps were not worn by the Romans for many ages. When the rain or sun was troublesome, the isppet of the gown was thrown over the head. The the lappet of the gown was thrown over the nead. And same usage prevailed among the Greeks, where, at least during the heroic age, no caps were known. The general use of caps and hats in Europe is referred to the year 1449, when they were used at the entry of Charles VII, into Rouen. From that time they began to take the place of chaperons or hoods. When the Charles VII. into Bouen. From that time they began which it is tound. In length it usually measures about to take the place of chaperons or hoods. When the two feet ten inches. The capercallie may lay claim to comp was of relvet, it was called mortier; when of wool, simply bonnet. None but kings, princes, and knights were allowed to use the mortier. The cap was the grandeur and boldness, beside which every Gulkus head-dress of the clergy and graduates. Pasquier says domesticus sinks into insignificance. Its plumage is that the giving of the cap to students in the universities denoted that they had acquired full liberty, and black, the neck and breast black, tinged with a rich grand. The templet attice, unlike its more reasher. were no longer subject to the rod of their superiors,— in imitation of the ancient Romans, who gave a pileus or cap to their slaves in the ceremony of making them free; said hence on medals Liberty was represented as holding out a cap in her right hand. Churchmen, members of universities, students, and others, wear square caps. The French clergy wear a shallow kind of cap cape. The French clergy wear a shallow kind of capelled a calotte, which covers only the top of the head The cap was also sometimes used as a mark of infamy. In France those who had been bankrupt were obliged to wear ever after a green cap, to prevent people from

to wear ever after a green cap, to prevent people from placing confidence in them in any future transaction; and if they should at any time be found without this cap, their protection was to be null.

CAP-APTM. (See ARMED AT ALL POINTS.)

CAP OF MAINTEMANCE OF DIGNITY, an ornament of state worn by royal or noble individuals on certain important occasions. It forms part of the British regalia, and was carried before the kings of England at the coronation. A cap of maintenance is also carried before the mayors of some cities.

# Capies

CAPACITY, ka-pus'-e-te (Lat. capax, capacious), in Phil., properly denotes the susceptibility of the mind of being affected by a particular class of emotions. It signifies literally "room for," and denotes the passive power of the mind as distinguished from faculty, which is active power. It is an aptitude to receive certain modifications of our conscioueness, in receiving which we are passive. The terms power, faculty, capacity, are more appropriately applied to natural than acquired capabilities, and are thus inapplicable to mere habits.

CAPACITY, LEGAL.—The legal capacity of persons depends upon their age or condition. (As to the first, see Age.) In the second case, the law has wholly or see AGE.) partially placed infants, married women, idiots, persons of uncound mind, and some others, under its protection, absolved them from the cousequences of certain acts committed, or limited their liability under contracts entered into by them. (The subject will be found referred to under the several titles of AGE, Com-PANY, CORPORATION, CONTRACT, DURESS, HUSBAND AND WIFE, INFANT, INSANITY, MARRIAGE, and OFFICER PUBLIC.)

CAPARISONED, ki-pdr'-e-zoned (Fr.), a term employed in Her. to denote a war-horse fully furnished for the field. In the Middle Ages, horses were caparisoned in a very superb and costly manner; and in some countries the horse caparison consists of the richest and most gorgeous materials.

CAPELIA, kā-pel'-la (Lat. capella, a she-goat), in Astron., a brilliant star of the first magnitude in the constellation Auriga.

CAPERCALLZIR, or CAPERCALLE, kā-per-kail-se (Tetruo urogalius), a bird of the Grouse species, whose uppellation is of Gallic origin, and means "horse of the wood," it is also called the Cock of the wood. Formerly, this maghificent bird was an inhabitant of the British isles, being principally found in the Highlands of Scotland, but has been for some time extinct there. It prefers the pine forests of Norway and Scandinavia, in which regions it is found in abundance. Several attempts have been made to introduce this bird again into Scotland, but without any satisfactory results, although the soil and nature of the country are well adapted to the purpose. As it is, a larger number of capercaille may be found in the regions of Leadenhall than in any other part of the United Kingdom. The food of the capercaille consists of the leaves of the Scotch fir, also various berries found in the North. The young have a more luxurious diet, feeding on auts, worms, and other insects. The size of this species varies considerably; in some cases a full-grown male (which is one-third larger than its mate) will scarcely weigh ten pounds; whereas it will sometimes exceed sixteen pounds. This discrepancy is greatly owing to the latitude in which it is found. In length it usually measures about two feet ten inches green. The female's attire, unlike its more resplendent mate, is humble, and is variegated with lowish-brown, white, and brownish-black. It would seem a pity that vigorous attempts were not made once more to introduce the espercailie into the United Kingdom.

CAPERS. (See CAPPARIS.) CAPIAS, kat'-pr-us (Lat. capio), to arrest a defendant. It is of various kinds. One is a writ called capius ad respondendum, before judgment. It cannot be issued unless the cause of action exceeds £20, and is no case without an affidavit made by the plaintiff that it does exceed that sum; nor can it be issued at all unless the defendant is about to abscord; in which case, on an affidavit of the cause of action, and stating cir-cumstances to show the defendant is about to leave the country, an order can be obtained for his arrest by an application to a judge of one of the courts of common law at Westminster, or a warrant for such arrest by an application to a commissioner in bankrupter, or a judge of a county court, except the courts for Mid-

# Capillaries

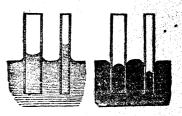

dlesex and Surrey. In either case a writ of capies must be issued; but if a warrant be obtained, the defendant may be arrested thereon without the writ, which must, however, be issued for hwith, and if no action be pending, a writ of summons also. The writ of capies must, if the debtor be in custody, be served in the state of th with the capies within seven days inclusive, from the date of the warrant. The defendant, on giving bail to the satisfaction of the sheriff in double the sum claimed. will be discharged; or, on giving bail before a judge, to satisfy the debt and costs, can obtain an order for his discharge; or he may apply to a judge of a superior court, commissioner in bankruptey, or county court judge, to have the writ or warrant set aside and vacated, if the application be made before arrest, or for his discharge out of custody if the application be made after his arrest. Another writ of capies is called capies ad satisfaciendum, and is issued on a judgment obtained in an action against the defendant, to arrest the defendant to satisfy the judgment. It cannot be issued in an action of debt unless the debt recovered exceeds £20, and the defendant cannot give bail, but must remain in prison until he be discharged under the Bankruptcy Act. (See BANKRUPT.) Another of such write is called capias ad withernam, issued in cases of distress for rent, or damage feasant by cattle, where the distress is carried out of the county or concealed, on which the sheriff might return that the goods or beasts were elvianed, elongata (carried to a distance), to places to him unknown, and thereupon the party levying could have a writ of capies in withernam, in ectito (or more properly repetitio) namio, a term which signifies a second or reciprocal distress, in lieu of the first which was eloigned. It was therefore recommand to the sheriff to take other goods of the distreinor, in lieu of the distress formerly taken and eloigued or withheld from the owner; so that there was distress against distress, one being taken to answer the other by way of reprisal, and as a punishment for the illegal behaviour of the original distreinor: for which reason goods taken in withernam could not be replevied till the original distress was forthcoming. As replevins can now be proceeded with in the county courts without writ, the old practice in such cases has fallen into desuctude. (See REPLEVIN.) It should be stated that in the old northern languages the word withernam is used as equivalent to reprisals.—(Sternhook, de Jure Sucon, I.1, c. 10.) A writ of capita pro fine, issued against a plaintiff for an amercement or fine to the crown for bringing a false action. This is abolished in some actions by 5 Will. & Mary, c. 12, and in all cases disused. The remaining writ of capies is a capies utlagatum issued against a person outlawed in any action, whereby the sheriff is commanded to apprehend him, and keep him in safe custody till the day of the return of the writ, and then have his body there to be ordered for

writ, and then have his condy mere to be ordered his contempt. (See Outlawer.)
Capitlaburs, kip-il-li-rees (Lat. capillus, a hair), in Aust., are the minute blood-vessels of the body, which form the connection between the extremities of the arteries and the voins. They vary in size from  $\frac{1}{\sqrt{3}n}$ th to  $\frac{1}{\sqrt{3}n}$ th of an inch in diameter, being smallest in the train and largest in the bones. It is in the capillaries that nearly all the changes in the blood take place. is in them that its carbonization is effected and animal heat produced, and from them that the bile, sweat, and wrine are secreted.

CAPILLABY ATTRACTION, a term applied to that part of Physics which investigates the phenomena produced when solid bodies are brought into contact with liquids. These phenomena are best observed in small tubes, about the diameter of a lair: hence the name. In all cases, although the phenomens are very varied in their mature, the result may be attributed to the mutual attraction of the liquid molecules for each other, and to the attraction between these molecules and solid substances. The following instances are examples of capillary attraction. When a solid substance is im-mersed in a liquid which wets it, as, for instance, a glass rod in water, the liquid becomes carred upwards towards the side of the solid, making its surface slightly concave, instead of being hofizontal. If, however, the liquid does not wet the solid, as, for instance, a glass rod dipped into mercury, the liquid is depressed against the sides of the solid and assumes a convex shape. The

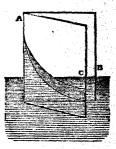

# Capital

surface of the liquid against the sides of the which contains it is also concave or convex, acc which contains it is also concave or convert it. If a to whether the liquid does or does not wet it. If a small tube, instead of a glass rod, is employed, these more apparent. The liquid phenomena become much more apparent. The liquid ascends, or is depressed, according to whether the tubes are moistened by the liquids or not, as repre-sented in the annexed illustrations. The amount of

ascent or depression is proportionately greater, according to the diameter of the tube. Gay-Lussac has demonstrated that liquids ascending or being depressed. in capillary tubes are governed by these laws. First, that a liquid ascends in a tabe when it moistens it, and that a liquid ascends in a table when it moistens it, and is depressed when it does not; secondly, that this ascent and depression are in the inverse ratio of the diameters of the tubes, so long as these do not exceed two or three millimétres; and, thirdly, that the ascent and depression vary with the nature of the liquid and the temperature, but that they are altogether independent of the thickness of the tube and the nature of the substance, provided that it is moistened by the liquid. These laws hold good in vacue as well as in air. Analogous capillary phenomena occur when two bodies of any given shape are immersed in water, provided the substance, provided that it is moistened by the liquid. bodies of any given shape are immersed in water, provided they are sufficiently near. If two parallel plates of glass are immersed in water at a short distance from one another, the water will rise between them in the inverse ratio of the separating distance. If the plates are immersed in mercury instead of water, a corre-

sponding depression is the result. If two glass plates, AB and AC, in-clined to one another at a small angle, as repre-sented in the accompanying engraving, he so immersed in a liquid which wets them that the line of contact between the two plates is vertical, the liquid will rise towards the summing of the angle of the two plates, and the curve from the highest part of the surface to the lowest will be the hyperbola. When two rise towards the summit

floating balls, both moistened by the liquid, are so near that the surface between them is not level, they are attracted towards one another. Balls that are not moistened by the liquid in which they float are also attracted in the same manner. Balls made of cork are instances of the former, and balls made of wax of the latter. If one floating ball is moistened by the liquid and the other is not, both balls are repelled. The theory of capillary attraction is one of the most diffi-cult in physics, and can only be completely treated by mathematical analysis. It has been more especially studied by Laplace, Clairont, and Poisson. The effects of capillary attraction are to be observed in many operations in nature. Insects can often move on the surface of water, because their feet are not wetted by the fluid, and a depression is caused, which buoys then up. A sewing-needle will float on the surface of water if covered with oily matter. Oil ascends in the water it covered with only matter. On ascenda in the wicks of lamps by capillary attraction, and water rises; in wood, sponge, biblious paper, and other porous substances, by the same force.

CAPITAL, kep'-ik-al (Lat. caput, the head), a term in Arch., applied to that part of the column which sus-

Capital Punishment

mounts the shaft, including the belt,—a part swelling outwards between the shaft and abacus, and the abacus itself. When the lower part of the espital assumes the appearance of being a continuation of the shaft, separated from it by an astragal or moulding, it is called the neck of the capital. In the five classic orders of architecture (see Architecture) the capitals form striking marks of distinction, and there is considerable difference in the treatment of the capital of the same order in Greek and Roman architecture, as will be seen presently.

The capital of the Tuscan order is very plain, consisting of a neck, on which is an ovolo moulding, support ing a square absous surmounted by a fillet. That of the Roman Doric is similar in form, but the neck is ornamented with rosettes and buds. The capital of the Greek Doric is far more elegant in appearance, consisting of a massive abacus supported by an echinus moulding that swells from the shaft, and is separated from it by three small amuleis. The capitals of the Greek and Roman Ionic are similar in appearance and general details. They are formed by volutes on two parallel faces, connected by curved or horizontal Between the spirals of the volute there is an echinus moulding, and, when a neck is added, it is enriched with tracery in relief. The abacus consists of an ogee moulding and fillet. The method of tracing the spiral of the volute will be found elsewhere. VOLUTE.) The bell of the Corinthian capital is richly ornamented with the leaves of the acanthus disposed in two rows, finished by four small spiral volutes in each face rising from the leaves below. Two of these curl outwards under the corners of the abacus, and two inwards, towards each other in the centre of each side. The abacus is formed of a cavetto, fillet, and echinus. The great point of difference in the Greek and Roman Corinthian capitals consists in the form given to the leaves. In the former they are pointed, and far more uatural in form than in the latter, in which they are beautifully rounded at the edges. The Composite beautifully rounded at the edges. The Composite capital is similar to the Corinthian, but the volutes at the angles are bolder and more ornate, springing out of a deep ovolo moulding which runs along the sides of the faces between the spirals. A description of the various forms of capitals used in architecture of different epochs, styles, and countries, will be found in the several articles devoted to this subject. (See ARADIAN, BYZANTINE, EGYPTIAN, HINDOO, GOTHIC ARCHITEC-TUBE, &c.)

CAPITAL, in Mil., a line drawn through any separate part of a system of fortification, such as a bastion, ravelin, lunette, &c., dividing it into two equal and similar parts. Thus the capital of a bastion is the similar parts. Thus the capital of a bastion is the straight line drawn from the salient angle through the

cuttre of the entrance in the rear.

CAPITAL, in Pol. Econ., may be defined as the accumulated savings of industry, capable of being employed either for the support of human existence, or as an instrument of production. In Com. the term is generally understood to mean the accumulated stook of every description with which a merchant or manufacturer, earlies on his business. In this sense it in facturer carries on his business. In this sense it infacturer carries on his business. In this sense it in-cludes not only the actual money employed, but the plant or machinery requisits for the production of commodities, as well as the buildings, raw materials, &c., indispensable for trade purposes. In short, it is wealth appropriated to reproductive labour. In the acience of political economy, capital has, however, a more exact meaning. It is difficult accurately to de-the it, and much valuable time has been wasted in fatile discussions upon the subject; but it will suffice the exact meaning that the machine that it comprehends are to say, in ordinary language, that it comprehends every species of wealth which a nation or community nosspecies of wealth which a nation or community pos-senses as the result of human exertion, and applicable to present and future uses. It represents the entire realth of a country, as apart from individuals. Upon reference to the most important treatises which have appeared upon this branch of political philosophy, we find capital usually divided into two kinds, viz.—1st, Bixed capital, consisting of the tools and instruments

the hands of their respective dealers, and of the money which is necessary for orivulating and distributing their to their final congumers." Fixed and circulating capital are dependent, and reast upon each other accordingto circumstances; and Mr. McCulloch lays it down as a cardinal dectride, that "it is only by their conjoised and powerful operation that wealth can be largely produced and universally diffused." He further says, "The quantity of industry, therefore, not only increases in every country with the furcess of the stock or capital which sets it in motion, but, in consequence of this increase, the division of labour becomes extended, new and more powerful implements and machines are invented, and the same quantity of labour is the hands of their respective dealers, and of the money thus made to produce an infinitely greater quantity of commodities. The ultimate object of the production or employment of capital is to provide for consumers, the wants or desires of whom vary with their condition of

fe." (See POLITICAL ECONOMY.)

CAPITAL ACCOUNT, in the financial affairs of railways and of public companies, signifies all that appertains to the capital stock. In railway concerns, for example, the money obtained for shares and upon debentures is lodged in a bunk, where it constitutes the capital account of the railway company, and serves as the source whence the directors of the company may obtain the means of purchasing the land, locomotives, rails, carriages—in brief, everything necessary to bring the undertaking up to the point of working. Upon the undertaking up to the point of working. Upon the opening of a line of railway for traffic, another account is commenced, called the revenue account, and which is frequently kept in another bank, and kept totally apart from the capital account. (See REVENUE AC-COUNT.)

CAPITAL LETTERS are those large letters of the alphabet that are employed in writing and printing, in place of small letters, at the beginning of proper names, sentences, lines in poetry, &c. Formerly was the custom to begin every noun with a capital letter, and this is still the case in German; but in English the capitals are now more sparingly em-ployed. The principal occasions in which they are used are at the commencement of proper names of persons, places, mountains, &c.; of adjectives derived from proper names; the opening of quotations; beginning of a sentence, and of each line in poetry; the pronoun I; and every principal word in the titles of hooks.

CAPITAL PUNISHMENT, in Crim. Juris., is the punishment of death,—the depriving the criminal of his life. It is so called from the head being that part of the body most commonly acted upon. The modes of in-It is so called from the measurement of in-body most commonly acted upon. The modes of in-flicting capital punishment have been very various at the different countries. Sometimes the object has been merely to accomplish the death of the criminal; at other times, it has been to prolong and add to his sufferings by cruci tortures, to satisfy a craving for vengeance, or as a public example. would be well-nigh impossible to enumerate all the ways which ingenuity has devised for the purpose of adding to or prolonging the sufferings of those who are being put to death; but among the more common may be mentioned, burning at the stake, crucifying, sawing in pieces, quartering alive, breaking upon the wheel, exposing to be torn by wild beasts, pinching to death with red-hot pincers. When the object is marely the with red-hot pincers. When the object is merely she infliction of death, hanging or beheading is usually had recourse to, and these are now almost the only modes employed in Europe. There are several important questions connected with capital punishments much agitated in the present day, which, however, our limits will only admit of our entering upon very briefly. There are many persons, whose opinion is entitled to the greatest weight, who hold that the state has no right to inflict death as a punishment for crime. right which a state possesses to punish for offences arises from the right which every one meturally has to protect himself from injury at the hands of another. In a state of nature, every individual has a right to protect himself from injury, and to repel force by force, and may even take away the life of another. meed by the labourer in creating the products of his minute, every individual has a right to meed by the labourer in creating the products of his protect himself from injury, and to repel force by industry, the machinery he makes and guides, and the protect himself from injury, and to repel force, and may even take away the life of another, if premises inscessary either to applicate his efforts or to necessary, to preserve his own. It was the consciousness of this great natural law that made Cain cry our hadam Smith explains as comprising "the provisions, against the severity of his punishment, saying, that made the consciousness of the provisions, and maintain of all kinds which are in "every one that findeth me shall slay me." When

# Capital Punishment

men come into a state of society, the right of protecting themselves from injury is transferred, by common consent, from individuals to the community, which, in this case, receives eractly the same power over all its members as each individual man naturally had to protect himself from others. This, of necessity, includes the punishment of death; and there is also the Scripruns injunction given by God himself to Noah and his children, that "Whose sheddeth man's blood, by man shall his blood he shod." Hence it is that the state has the right to punish murder by death; and practically In this country it is, happily, only in cases of murder that capital punishments are now inflicted. In Blackstone's time there were no fewer than 160 crimes punishable by death. There is more room to doubt whether capital punishments ought to be inflicted for Matthew Hale, "When offences grow enormous, frequent, and dangerous to a kingdom or state, destructive or highly pernicious to civil societies, and to the great insecurity and danger of the kingdom or its in-habitants, severe punishment, or even death itself, is necessary to be annexed to laws in many cases by the prudence of lawgivers." There are some who, while they do not deny the right of the state to inflict capital punishment, yet question its expediency, asserting that the desired end would be as well, or better attained in another way. The end of punishment is not to avenge past, but to prevent future offences. There are three ways in which this may be accomplished :-- 1. by reforming the criminal himself; 2. by preventing him from scain offending; and 3. by deterring others through his example. It is this last that is the principal object in view in all criminal punishments. Is this object, then, best obtained through capital punishment, or might it be better attained in some other way? Would the continued example of a living culprit, condemned to a lifetime of labour as a slave to repair defined to a metime of innour as a sare to repair the injury done to society, have a greater effect in deterring others from crime than the sight of an ex-ecution? It is here, in our opinion, that the strength of the arguments against capital punishment lies. We believe that it is scarcely possible for those for whose benefit the example is specially intended, for wiose benefit the example is specially intended, in any measure to realize the feelings of one under sentence of death; and we may easily suppose that they will not strive to do so. While, doubtless, the culprit himself would gladly welcome any kind of servitude, however hard, in exchange for certain death, we believe that generally the culcoker would regard that mode of death vastly preferable to a prolonged period of suffering, from which there was no hope of deliverance. Funishments of long duration are much more terrible to the spectator than those that are severe, but soon over. The intenseness those that are severe, but soon over. Another make such an impression upon the mind as its long continuance. Many think that they could meet death with firmness and intrepidity, who would shudder to think of perpetual slavery. The would shudder to think of perpetual slavery. The terrors of death make so slight an impression that it soon passes out of the mind, especially if moved by desire or passion. The tendency, too, of a public execution is (except in rare cases) rather to excite the pity and compassion of the spectators for the sufferer than detestation of his crime; and there have been cases, too, where persons have been of so deprayed tastes, as that the sight of a public execution has even moved them to desire what they regarded as the color of such an exhibition. It has been advanced by Sir Samuel Romily, against those who hold that the state has no power to inflict capital punishment, that if, been advanced as the color of moved them to desire what they regarded as the color ment is, or can be, greater than that of death; but to the spectator, perpetual slavery seems much the severer of the two. The spectator collects all the miserable moments of a slave's life into one point, while to the slave himself they are diffused over a long period; the sufferer, etco, becomes, by habit, callous to his misfortunes, and even finds sources of consolation, of which the onlockers are ignorant. While, therefore, perpetual slavery would serve effectually to prevent the criminal from further offend. long pariod: the sufferer, stoo, becomes, by habit, and children, if there be any with the garrison. The callous to his misfortunes, and even finds sources of besiegers generally take possession of the arms and consolation, of which the onlookers are ignorant, stores remaining in the place. A convention is a sour while, therefore, perpetual slavery would serve efforcapitulation by which the general of an army oscial factually to prevent the criminal from further offend-pying any district agrees to withdraw his troops and

# Capitalstign

ing against the laws, such a proceeding would doubt-less be the more merciful to him, and would also, we believe, serve more effectually as a means of deterring others. It has been well said, that "a penal systems ought to sim at economizing pain by diffusing its largest amount of salutary terror, and thereby deterring as much as possible from crine at the smallest expense of punishment actually inflicted." The criminal would also be, in this way, able to contribute something for the good of society, whose laws he had bricken, and might also have time to prepare himself for that tribunal before which he had yet to appear. There would also be an important gain in the greater certainty of the punishment; for "crimes," says Beocaris, "are more effectually prevented by the extensity than by the serving of cupital punishment," The very everity of capital punishment prevents it in many cases from believe, serve more effectually as a means of deterring than by the severity of punishment." The very severity of capital punishment prevents it in many cases from being carried out, and thus allows some hope of escape, even to the most guilty. The arguments against capital punishments will be found shy stated by Beccaria, "Essay on Crimes and Punishments;" and those on the opposite side by Jeremy Bentham, "Estamate of Punishment." (See Punishment.)

CAPITATION, kā-pit-ai-shum (Lat. caput, the head), denotes a thing that is applicable to all persons—literally, to every head. A capitation or poll-tax is a tax levied on persons by the head, without reference to property or other circumstances: it may be on every

property or other circumstances; it may be on every one; on all males; on all above a certain age, &c. In France the ancient capitation-tax is now replaced by

more approved modes of taxation.

CAPITOLINE GAMES, kd-pit'-o-line, annual games instituted by Camillus, and held by the Romans in honour of Jupiter Capitolinus. They commemorated the preservation of the Capitol from the attacks of the Gauls. The name was also given to certain games which were relebrated every five years. Nerv endeavoured to introduce a new method of computation of time from this quincumprise schaftering leads that the computations.

of time from this quinquennial celebration.

CAPITULAR, kū-pib-u-lar (Lat. caput, the head), is a term frequently employed on the continent to de-

signate a major canon or probendary, a capitular member of a cathedral or collegiate church.

CARITULARIES, kip-it-u-la-ries (Lut. capitularia) were certain laws or ordinances issued by the French kings of the first and second Frankish races, for the administration of civil and ecclesiastical affairs. These capitularies were made in the assemblies of bishops and lords of the kingdom. The best known are those of Charlemagne and Louis. Ansegisus, abbet of Fontenelles, made a collection of these in 827, and other collections were made subsequently. Bishops were also accustomed to give the name of capitularies to the rules which they drew up from the canons of coun-cils for the regulation of their own dioceses.

CAPITULATION, kāp-it-u-lai'-shun (Lat. capitula, heads, from caput), in Mil., the act by which an officer in command of a fortress or body of troops surrenders to the enemy. The terms of the surrender are stated in a series of articles, to which the expression is more particularly applied. The governor of a fortress is justified in capitulating to an enemy when he has defended his post as long as the ammunition, provisions, and resources of the place will permit; for when the walls have been breached, and there is no hope of obtaining relief, continued resistance would be an act of madness and folly, which would sooner or later compel him to surrender at discretion, placing himself and his forces entirely at the mercy of the enemy. A white flag is the sign that the besieged desire to ca-pitulate. The articles are generally drawn up by pitulate. The articles are generally drawn up by officers deputed for the purpose by the general commanding the investing army on the one hand, and the governor of the fortress on the other. The terms generally depend on the nature of the case, but, in most instances, the beleaguered troops are permitted to march out with drums beating and colours flying, and the officers are allowed to retain their private preparty. Protection is obtained for all, and considerate treatment for the sick and wounded, and the women considerate

# Capitulum

evacuate it in favour of a superior force, which he cannot hope to oppose with success in the field.

Captrollum, ki-pit'-u-lum, in Bot., a kind of inflorescence, consisting of a close terminal collection of flowers surrounded by an involuce. It constitutes the compound flower of Linnaus, and is also known under the names anthodium and head. The receptacle bearing the flowers may be flattened, as in the cotton highle, or alightly convex as in the shapenile. thistle; or slightly convex, as in the chamomile; or globular, as in the American button-bush; or of other form hence the numerous modifications of the capitulum. In the nat. ord. Composite the flowers are always arranged in capitula.

arranged in espituis.

\*\*Capproblem or käp\*no-män-se (Gr. kapnos, smoke; mantrie, divination), a species of divination used by the ancients. If the smoke ascending from the sacrifice was thin and light, and went up in a straight line, it was considered to augur favourably; but if went in any other direction, it was an evil omen. Some practised this kind of divination by throwing propriets is sample, seeds on the fire, and watching the

poppy or jasmine seeds on the fire, and watching the direction of the smoke in the same way.

Carnonge, or Karnomor, käp'-no-mor (Gr. kapnos, smoke, and moira, a part), a colourless oil of peculiar odour, resembling that of ginger, discovered by Reichenhach, amongst other products, in heavy oil of tar. It is limpid and volatile, insoluble in water and solution of nates, but dissolving readily in also believed. 'It is limpid and volatile, insoluble in water and solution of potash, but dissolving readily in alcohol, ether, and the essential and fixed oils. Its specific gravity is slightly below that of water. It boils at 345° Fahr, and distils unaltered. It burns with a sooty flame, and is perfectly neutral in its reactions. It is obtained by distilling a solution of crude creosote in potash and with water. With sulphuric acid it forms a purple-red solution. It has not yet been satisfactorily analyzed. Caponnière, &p-on-yaire' (Fr.), in Mil., a pussage made scross the ditch of a fortress to any of the contworks, such as the ravelin in front of the curtain

outworks, such as the ravelin in front of the curtain connecting any two bastions. It is composed of a double line of parapets about eight or nine feet high, with a banquette from which the defenders may fire. Externally, the earth slopes from the top of the parapets to the bottom of the ditch, forming a glacis on either side of the work. When only one parapet is made, it is called a demi-caponnière. Sometimes the expansive takes the form of a covered culture of made, it is called a demi-caponniere. Sometimes the caponnière takes the form of a covered gallery of masoury, with the sides loopholed for musketry. In fleld-works they are formed of palisades, or consist of treaches with a bomb-proof covering.

\*\*Capora\*\*, \*\*k^\*-pote\*\* (Fr.)\*, a long cloak made of muslin or black silk bordered with lace. It is worn by ladies

en negligic. The name is also given to a large horizontal hat with a heavy fringe of lace; and over-conts worn by the French soldiers are called capotes.

CAPPABIS, kap'-pa-ris, in Bot., the Caper-bush, the

CAPER PLANT.

typical gen. of the subord. Capparen, of the nat, ord. Capparidacen.
The pickled flower-buds of various species are used under the name of capers. Those eaten in Europe are the produce of *C. spinosa*, a trailing shrub which grows in rocky places in the south of Europe. It is the only species of the order found on the north of the Mediterranean, The capers used in Barbary are obtained from C. Fon-tanesti, and those used . The latter species is

LARRY FIRST.

Lancait, and those used la Egypt from C. egyptiaca. The latter species is believed to be the hyssop of Scripture.

CLEVANIACIE, http://doi.org/10.10000/10.10000/10.10000/10.10000/10.10000/10.10000/10.10000/10.10000/10.10000/10.100000/10.10000/10.100000/10.10000/10.100000/

Caproic Acid

rous, placed on a hemispherical or an elongated disk : the ovary 1-celled, the style thread-like or wanting; the fruit is either pod-like and dehiscent, or bacate and indehiscent. The two kinds of fruit have led to a the fruit is either pourme and demonstration to be and indehiscent. The two kinds of fruit have led to a division of theorder into two sub-orders; vis., Closuser, characterized by a capsular fruit, and Capparese, by a baceate fruit or berry. In their properties the Capparedacea greatly resemble the Crucifera, being generally pungent, stimulant, and autiscorbutic. Some are aperient, diurctic, and authelmintic.

are aperient, dureric, and sattachments.

CAPRA, the Goat. (See GOAT.)

CAPRIC ACID, kip'-rik (Lat. capra, a gost, terminal icus), a volatile fatty acid discovered by Chevreni amongst the products of the suponification of butter.

It is also procured by acting on oleic acid or oil of rue with write acid. It is also procured by acting on oleic acid or oil of rue with write acid. with nitric seid. It is also found in small quantities in the fatty acids of cocos-nut oil. Capric acid crystallizes in fine needles, which fuse at 86°, giving out an odour resembling that of a goat. It is sparingly soluble in boiling water, from which it separates in glistening It has been named capric seid from its peculiur odour, but is now generally termed ratic acid, from being easily contounded with caproic and caprylic acids, and from being the acid of which oil of rue is the aldehyd. (See ALDRHYDE.) CATRICCIO, kā-prit'-tcho (Ital.), in Mus., an irregular

species of composition, in which the composer, without any other restraint than the boundary of his imagination, continually digresses from his subject and runs wild amidst the ferrour of his fancy. Perhaps the finest specimen of this form of musical composition is Mendelssohn's B minor C. for orchestra and pianoforte.

CAPRICORNUS, kap-re-kor'-nus (Lat. capricornus, & goat), a constellation in the southern hemisphere, from which the tenth sign of the zodiac, between 270° and

CAPRICORNUS.

300° of longitude from the first point of Aries, originally derived its name. The sun enters the winter solstice in this sien.

CAPRIFOLIACE E. kap-ri-fo-li-ai'-se-e (Lat. caper. goat: folium, leaf, in reference to the climbing habit of the plant), in Bot., the Honeysuckle fam., a nat. ord. of dicotyledonous plants in the sub-class Corolliflors, consisting of shrubs with the following general characters: -- Leaves opposite and exstipulate; calyx superior, 4-5-cleft, usually bracteated; corolla monopetation, 4-5-cleft, tubular or rotate, regular or irregular, rarely polypetalous; stamens 4-5, inserted on the corolla, and alternate with its lobes; overy inferior, 1-5-celled, usually 3-celled, often with I orule in one cell and several in each of the others; fruit generally a berry, dry or succellent, indehiscent. There are 18 genera and about 220 species, chiefly natives of the northern parts of Europe, Asia, and America. They often have showy flowers, which are commonly sweetscented. Many are cultivated in our gardens and shrubberies; as Honeysuckles, which are species of the genera Caprifolium and Lonicera; Guelder-roses, specess of viburnum; the Laurustinus (Viburnum Thus); the Snowberry (Symphoricarpus racemosus); and the common Elder (Sambucus nigra). Some of the plants are emetics and mild purgetives; others are astringent;

others sudorific and diuretic; and a few are aerid.

CAPROIC Acts, kip-ro'-ik (O<sub>2</sub>H<sub>1</sub>,O<sub>4</sub>), an acid obtained during the saponification of butter or coocs-nut oil, or by oxidizing cleic acid by nittle arid. It is

# Caproie Alcohol

Equid at ordinary temperatures, has a sweet and pungent taste, and a characteristic odour of acid perspiration. It boils at 335° Fahr., and its specific gravity is '830. It is best prepared by boiling cyanide of amyl with alcoholic solution of potagh. Ammonia escapes, and a crystalline residue of caproate of potagh is left behind. The salt is dissolved in water, and sulphuric soid is added, which unites with the potash, leaving the caproic acid floating on the surface. Caproic acid forms monobasic salts with the

CAPBOIC ALCOHOL.—Caproic alcohol is the hydrated exide of caproyl or hexyl, the sixth in the series of the homologous radicles. It is often called hexylic alhomologous radicles. It is often called herylic al-cohol, It is obtained from the fermented mark of the cohol. It is obtained from the fermented mark of the grape, along with propylic, butylic, and amylic alsohols, from which it is separated by fractional distillation. It is a colourless aromatic liquid of specific gravity 832, and it boils at 302 Fahr. By heating it with hydrate of potash, caproate of potash is formed, in the same manner that acetate of potash is formed from vinic alcohol when it is heated with hydrate of potash, acctic acid bearing the same relation to vinic alcohol that caproic acid does to caproic alcohol,

CAPROLC ETHER .- Caproic ether is the caproate of ethyl, and must not be confounded with caproylic other, which would be oxide of caproyl—a substance as yet unknown. It is prepared by distilling caproute of baryta, sleebol, and sulphuric acid together. It is a limpid, oily fluid, boiling at 324° Fahr., and possessing an agreeable fruity odour, resembling that of pine-

apple.

CAPROYL, or HEXYL, kip'-roil, hex'-ile (C12H18).—
The radicle of caproic alcohol is termed hexyl, from being the sixth of the homologous radicles forming the alcoholic series. It is obtained by the electrolysis of conunthylate of potash as a fragrant oil, hoiling at 397° Fahr. It is a permanent substance, and remains undecomposed when submitted to the action of sulphuric or moderately strong nitric acid; but by mixing the two it is changed into a fatty acid, supposed to be caproic acid.

CAPRYL, or OCTYL,  $k\ddot{a}p'$ -rile ( $C_{10}\Pi_{17}$ ), the eighth radicle of the homologous alcoholic series, obtained by treating the chloride of capryl with metallic sodium. Its properties have not yet been thoroughly investi-

gated.

gated.

CAPRYLIC ACID. kdp-ril/-ik (C<sub>16</sub>H<sub>16</sub>O<sub>4</sub>), one of the volatile acids obtained by Chevreul during the saponification of butter. It is also obtained by the action of nitric or oleic acid. It is a colourless, cily liquid, insoluble in water, but soluble in alcohol and ether, with a disagreeable sudoriferous smell. It becomes solid at 50° Fahr., and boils at 457° Fahr. It is prepared by decomposing caprylate of baryta with sulphuric acid. It forms monobasic salts with the bases, which have not as yet been expanded.

which have not as yet been examined.

CAPRYLIC ALCOHOL.-Caprylic or octylic alcohol is the hydrated exide of capryl or octyl, as vinic alcohol is the hydrated exide of capryl or octyl, as vinic alcohol is the hydrated exide of ethyl. It occurs in small quantities in the fermented mark of the grape; but its most available source is eastor oil, which contains a compound of glycerin and ricinolic acid. This com-pound, when heated with hydrate of potash, is resolved pound, when heated with hydrate of potash, is resolved into hydrogen, sebate of potash, and octylic alcohol. The following is the process for its preparation, recommended in Miller's "Elements of Chemistry," vol. iii. p. 129:—"Castor-oil is saponified by means of potash or sods, and afterwards an excess of the hydrated alkali is added, amounting to one-half the oil used. The mass is heated in a retort, and an oily liquid covered with water distils over. This oily liquid, which is the octylic alcohol, is rectified several times with potash, until the residue is no longer coloured brown. Octylio alcohol is a colourless liquid of a powerful aromatic adour. It is insoluble in water, but dissolves readily in acetic acid, other, and alcohol. Its spec. grav. is '823, and it boils at 356°.

\*823, and it boils at 356."

\*Capertico Erner.—Caprytate of ethyl is generally called by this name; but by doing so it is apt to be confused with true caprylic ether, which would be oxide of capryl. Caprytate of ethyl is a colourless liquid, with an agreeable odour of pineapples. Caprylic add forms ethers with methyl and amyl, which have been investigated by Walls and others.

497

Caps, Percussion

Care, Pracussion, kaps, per-kus'-shus (Lat. percenters, to strike), small cylindrical cases of copper, some taining a little detonating mixture at the bottom of the cavity. These cases fit closely over the nipple of the fowling-piece or rifle, and explode when struck sharply by the descending hammer, igniting the powder with which the piece is charged. The detonating composition used in the struck struck is the struck of the struck tion used in the manufacture of percussion caps consists of a mixture of fulminating mercury, chlorate of DETONATING POWDER, FULMINATING MERCURY.)
The following is the method used in making the caps for the use of the British army; the process is similar for all kinds of caps, but for fowling-pieces the copper case is thinner and smaller in size than those made for government, which also have a projecting rim round the edge of the cap, by means of which they are more easily taken from the cap-pocket, and adjusted on the nipple of the rifle. The common cap is destitute of this rim. The copper is prepared in sheets two feet long, and a little more than three inches in width, which are pressed and completely flattened between which are pressed and completely flattened between rollers. By means of steel punches in the form of a cross, measuring three-fourths of an inch between the extremities of opposite arms, the copper is cut-into little pieces of this shape, which are heated for a considerable time in metal cylinders, and then thrown into cold water to harden. They are then plunged into a bath of sulphuric acid and water, which removes the oxide with which the pieces have become coated during the last-named since of the process; and after this the last-named stage of the process; and after this they are dried and oiled. The next step consists in moulding the copper crosses into caps by means of dies, after which the oil is removed by shaking them in sawdust, and the caps are arranged in a perforated plate containing 1,000 holes, in order to be charged with the detonating mixture. This preparation is pressed into the bottom of each cap by the action of another plate studded with projections that fit into each cap as it lies in the perforated plate stready mentioned. Another similar plate, with the projections meared with varnish, is then pressed into the caps. The varnish forms a coating over the fulminating composition to protect it from damp and the action of the weather. After the varnish has been introduced, it is hardened by submitting the caps to the action of a steam-bath, and glazed by the introduction into each cap of a polished nipple, which revolves by the action of a lathe. The caps when finished are packed in small cases, each containing twenty-five. army a cases, each containing wenty-tive. It this army a case is allowed to every twenty rounds of blank or ball cartridge, to cover loss arising from caps missing fire, or other causes. For private use they are packed in boxes containing from 500 to 1,000 each, and numbered to correspond with the nipple for which each cap is the standard of the captain in this district. size is suited. The invention of percussion caps was brought about by an attempt made by the French in 1793 to substitute a fulminating powder for gunpowder, in consequence of the difficulty that existed in Franco at that time of procuring sattpetre. The Rev. Mr. Forsyth, a Scotch clergyman, conceived from this the idea of igniting the charge of powder by means of a detonating mixture exploding by percussion, and in 1807 he patented his process, having laid his plans before the Board of Ordnance, and received encouragement to proceed in the development of his inventi The great difficulty to be overcome was that of insuring the explosion of the detonating powder, which was eventually effected by placing the mixture in a cap or cell of metal. Before 1825 the use of copper caps and the percussion lock had become general, and the old musket with the flint look, which had rendered such efficient service in the Peninsular and other wars, was officient service in the Peninsular and other wars, was superseded by a more efficient arm,—the percussion musket, or Brown Bess, which gave way to the Enfeld, which, in its turn, has been superseded by the Snider rifle, and even improvements on the Snider rifle, The principle of the percussion lock is now applied to heavy ordnance, and many kinds of shells have been prepared to explode by detonation on striking any object, instead of by means of the fuse; among which, that which was invented by Capitain Norton may be especially mentioned. One of the exhibitors of percussion-caps at the Great Exhibition of 1851 made the very ingenious calculation that the

## Capsicine

total manufacture of persuasion-caps for sporting-guns in Europe may be estimated at 1,300 million yearly, requiring 396,000 lb. of copper. (See SHELL.)

CAPSCINE, hap're-sene (from copsicum, derived from Gr. kapte, I bite, in allusion to its pungency), an alkaloid found in the capsules of the various species of captioum used in the manufacture of cayenne pepper. It has a burning taste; is insoluble in water and ether, but soluble in nicohol, and may, when quite pure, be orystallized. It forms salts with nitrie, sulphurie, and acede acids. Its composition is unknown.

Carricum, kap'-se-kum (Lat., a bridle), in Surg., is a single split cloth bandage, used to support the lower jaw; so called from its resemblance to a bridle.

CAPSECUM (from Gr. kapto, I bite), in Bot., a gen. of plants belonging to the nat. ord. Solunaceæ, consisting of numerous species, all remarkable for the

CAPSICUM PLANT.

presence of an acrid resin Capsicine in their called fruits, which are hot, pungent, and stimusous. Though now extensively cultivated in many parts of the Old World, the various species are supposed to be na-tives of South America. The officinal capsicum, the C. annuum of Linnaus, or the C. fastigiatum of Blume, has oblong-cylindrical fruits, not an inch long in the most valuable varieties, but two three inches long in others. commonly sold as Chillies, and are used to make a hot pickle, and the liquid known

as Chili vinegar. Cayenne pepper consists of the powdered fruits of several species of Capsicum, found in the West Indies and South America. In medicine, the fruit of the capsicum is used as a counter-irritant: with salt as a stimulant in scarletina; as a gargle in relaxed sore-throat; and in the form of Cayenne fozenges.

CAPSTAN, käp'-stän (Fr. cabestan), a strong column of timber, shaped like a truncated cone, passing through the deck of a ship, and turned by levers or bars, which pass through holes pierced in its upper extremity, serving, by means of a cable which winds round the barrel, to weigh the anchor and draw up weights, &c. Men-of-war have commonly two capstans, the largest of which, called the main capstan, is placed behind the main-mast, standing upon the first deck, and reaching four or five feet above the second: this is also called the double capstan, because it has two drumheads, and serves two decks for drawing up anchors, and because its force may be creatly accelerated by applying hands on each deck. The other is the jeer, or title capetan: this stands on the second deck, between the main and mizen musts. There is also a flying capitan, so called from its being movable to any part of a ship.

CAPSULE, kap-sule (Lat. capsu, a chest), is a membranous production, inclosing any part like a bag; as the capsular ligaments inclosing the synovia of the joints, the capsule of the crystalline lens of the eye

CARSULE, in Bot., a superior, one or more-ceiled, many-seeded, dry, dehiscent fruit. It is syncarpous, that is, formed of several carpels united together. The dehiscence or opening of the capsule may either take place by valves, as in the forglove, primrose, and rhododendron, or by pores near the summit, as in the poppy and snapdragon. The distinctive name of Pyxis or Pyxidium has been given to a beautiful kind of capade, which opens as if out around near the summit, and presents the appearance of a cup with a lid. Examples of the latter may be seen in the pimpernel and henbane. The capsule is one-celled in the mignonette, heart scase, and gentian; two or more celled in the scrophularia, colchicum, iris, and datura. It is a very common form of fruit, and is found almost universally in some natural orders; such as Papaverusea, Caryo-phyllacea, Primulacea, Scrophalariucea, Liliucea, Iri-dacea, and Gentianacea.

## Captive

a company of infantry, a troop of savalry, or a battery of artillery.—In Mar., it is given to the naval officer that commandes a ship of war. Commanders in the navy are called captains by countery; but the term properly belongs to officers occupying the intermediate rank between commanders and admirals, who ware formerly called post-captains. The name is improperly given to the chief officer of a merchantman, whose propers mapply their is that of market. proper appellation is that of master. Many suitors on board ship holding some petty place of authority among others, are called captains; as the captain of the gun, captain of the forecastle, &c. In the army, the captain has the complete control of the internal economy of his company in matters of discipline. clothing, arms, accourtements, barracks, billeting, and accounts. In this he is assisted by his subattering, —the licutement and ensign in infantry, licutement and cornet in cavalry, and first and second licutements in engineers, artillery, and marines. In the artillery there is an officer called the second captain, formerly termed the captain-lieutenant. The captain is responsible to the major for the good order of his company in every respect. The captains in both services share the advantages derived from a general brevet. The value and method of purchase of a captain's commission, and rate of pay, will be found clsewhere. (See COMMISSIONS, NAVY.) It is necessary that an officer should have been an effective subalters for two years before he can attain the rank of captain. The naval captain holds a post of greater importance than a captain in the army, as it involves a far greater amount of responsibility; the latter being responsible for his company only, while the former is answerable for the safety of his ship and the discipline of the crew, and has the management of everything on board. The captain in the army ranks with a lieutenant in the navy, and a captain in the navy ranks with a lieutenantcolonel in the army until he has held his commission three years, when he ranks with a full colonel. several ships compose a fleet under the command of an admiral, the captain of the ship in which the admiral hoists his fing is called the flag-captain, and takes pre-cedence of others in the fleet of the same rank. The ceptain of the flect is an officer through whom the admiral issues his orders, holding a position similar to that of the principal side-de-camp to a general officer or chief of the staff.

CAPTION,  $k\ddot{a}p'$ -shun (I at. coptio, a taking).—When any commission at law or in equity is executed, the commissioners subscribe their names to a certificate, testifying when and where the commission was executed; and to is a called a caption; also where a man is arrested, the act of taking him is called a caption. There is also the caption of an indictment, which is the setting forth of the style of the court before which the jurors make their presentation. It is also the memo-randum at the foot of an affidavit or statutory declaration, subscribed by the judge, commissioner, or other person before whom it is made, showing the time and place at which it is made.

CAPTION, in Scots law, is a writ issued under her majesty's signet, and in her majesty's name, at the instauce of a creditor in a civil debt, for the apprehension and imprisonment of the person of a debtor until he pay the debt. By a legal fiction, no person in Scotland could be imprisoned for a debt purely civil, unless in royal boroughs or under small-debt decrees; and hence the imprisonment was nominally for the act of rebellion in delaying obedience to the command of the sovereign to pay the debt, and hence, too, it was only granted after a charge of horning. This form of proceeding is now rather matter of history than of custom, baving fallen into desuctude since 1838, the power of imprisonment having been then extended to sheriffs by 1 & 2 Vict. c. 114. Caption is also the name of a same mary warrant of imprisonment issued against an ag to return the papers of a process or lawsuit, which have been borrowed by him and are unduly detained.

CAPTIVE, kap'-tiv (Lat. captives; Fr. captiv), a person taken by an enemy in war. Formerly, captives in war became the slaves of those who took them, or were sold as slaves. Often they were subjected to the greatest oruelties, or were put to death in many inhuman ways. Great numbers of them were sometimes offered as CAPTAIN, kapt's (Lat. caput, the head; Fr. captions), the title given, in Mil., to an officer commanding specifices to the gods of the victors. It seems to have

been a custom occasionally resorted to in the East, to make the captives lie down on the ground and then to put to death a certain portion of them, which was measured by a line or determined by lot. It was in accordance with this custom that Dagid, as we are told, "amote Mosb, and measured them with a line, wind, "emore Mosh, and measured them with a line, casting them down to the ground; even with two lines measured he to put to death, and with one full line to keep alive" (2 Sum. viii. 2). Sometimes, as referred to by Virgil (Eneid, b. viii. 485 et seq.), the living and the dead were coupled together, face to face and hand to land, till the living became as the dead. Somewhat have a with the Romera their needs were coupled. to hand, till the living became as the dead. Some-times, as with the Romans, their necks were exposed to the soldiers to be trampled upon; sometimes they were loaded with irons, and sometimes, as in the case of Samson, their eyes were put out. They were often of Samson, their eyes were put out. They were often stripped naked, and made to travel in that condition, exposed to the hurning heat of the sun by day and to the chilling cold by night. There are frequent references in the Old Testament to the modes of treating captives, and a knowledge of these serves to throw light apon many passages of Scripture prophecy; as when Isaiah describes the character and work of the promised Messiah:—"He hath sent me to heal the broken-hearted, to preach deliverance to the captives, and recovering of sight to the blind, to set at liberty them that are bruised.

CANTIVITY, kap-tiv'-e-te (Lat. captivitas; Fr. oc twite), a term employed in Scripture to denote the punishment indicted by God on the Jews for their dolatry and wickedness, by allowing them to be re-moved out of their own land. This was one of the means frequently adopted by eastern monarchs in order to establish their power over vanquished nations; viz., to transport an important part of the popula viz., to trunsport an important part of the population of those nations into their own dominions; and sometimes, also, they established in the vacated territory a portion of their own subjects. To a people like the Hebrews, whose religion was connected with particular places, such a proceeding must have been particularly severe. When personally removed from Jerusalem, they could no longer obey their sacred law in many of its most vital points, and many others they were forced to modify by reason of their changed circumstances. Their first captivity was that of Egypt, from which they were rescued by Moses; but this is to be regarded rather as a providential dispensation than as a penal evil. We read of six captivities that took place during the government of the judges; but the two most signal captivities of this people were those of Israel and Judah after they had been formed into separate kingdoms, and are known as those of Assyria and Babylon. That which is called the first captivity was not brought about by a single removal of the pop-ulation; on the centrary, the kingdom of Irruel was invaded on several occasions by the kings of Assyria. About B.c. 740, Tiglath-Pileser carried off the more distant trans-Jordanic tribes to Assyria. His suc-cessor, Shalmanezer, twice invaded the kingdom which remained to Hosea. He attacked and reduced Samaria after a siege of three years, B.c. 721, and carried off into Assyria and Media the king and the remainder of the ten tribes, and their place was supplied by colonies from Bubylon and Susis. This was the end of Israel as a kingdom. More than a century elapsed before the second or Babylonish captivity, which overtook the kingdom of Judah. Two distinct deportations are mentioned in the second book of Kings, three in Jeremiah, and one in Daniel. The two principal deporta-tions, however, were—1. That which took place B.c. 598, tions, however, were—1. That which took place n.c. 598, when Jehoiachin, with all the nobles, soldiers, and artificers, were carried away; and, 2. that which followed the destruction of the temple and the capture of Zedekish, n.c. 598. The seventy years of captivity predicted by Jeremiah are dated by Prideaux from n.e. 606. The Jewa in their captivity were not treated as slaves, but as colonists. They had elders and judges among themselves, who governed them and determined among themselves, in governor the among themselves, in disputes according to their own laws. There was nothing to hinder a Jew from rising to the highest eminence in the state, or holding the most confidential offices. The Babylonish captivity was brought to a

a subject which has given rise to much discuss Many attempts have been made to discover them his as a distinct community in some distant part of the interior of Asia. The most probable opinion, however, seems to be that the great mass of them became i seems to be that the great mass of them become as-sorbed in the nations among whom they were plantled; but that many of them returned with the children of Judah, after the Babylonish captivity, to their own land, by which means they became one people, the event probably referred to by Ezekiel when he says, "Thus saith the Lord: Behold I will take the children of I read from arong the heather whither they ha of Israel from among the heathen whither they begone, and will guther them on every side, and bring them into their own land; and I will make them one ation in the land upon the mountains of Israel."

Even of the children of Judah, it is calculated that the gr at majority of them chose to continue in Assyria, and those of them who kept up their national distinctio s were known as the "Dispersion," or the "Dispersed among the Gentiles." The character, language, and habits of those that returned, of the Jewish people, were very markedly changed by the captivity. Their love for agricultural pursuits had declined, and a taste for commercial enterprise had taken its place. A new and eeper feeling of reverence for the letter of the law o. Moses had taken possession of them, and a profound hatred of their old sin of idolatry. The sufferings entail d upon the Jewish people under the Romans far exceeded that of any other captivity which they underwent; for they were then reduced to a real state of hondure. According to Learning 1100 000 see of bondage. According to Josephus, 1,100,000 men fell in the siege of Jerusalem by Titus, and 97,000 were captured during the war. Of the latter, many were cast to wild beasts or butchered in the amphitheatres; others were doomed to work as public slaves in Egypt, and only those under 17 years of age were sold into private bondage. An equally dreadful destruction fell upon the remains of the nation, which had once more assembled in Judga, under the reign of Hadrian (A.D. 133), as related by Dion Casaius. By these two savage wars the Jewish population must have been effectually extirpated from the Holy Land itself, a result which did not follow from the Babylonian captivity. Since that time, the Jews have been, with few and partial exceptions, a despised, oppressed, and a degraded people, scattered among the nations of the earth.—Ref. Calmet's, Smith's, and Kitto's Dictionaries of the Bibic.

CAPTURE, kap'-tsher, the act of taking or seizing; as the capture of a vessel, of booty, of an enemy by strategem, surprise, or force. (See Boory, Prize.)

CAPUCHINS, kip-u-sheens', a branch of the religious order of the Franciscans, so called from the capue,

order of the Franciscans, so caned from the capuco, a sharp-pointed cap or covil wherewith they cover their heads, having in addition the ordinary franciscan babit. They owe their origin to Matthew de Bassi, a Franciscan monk of Urbino, who, baying resolved upon a more literal fulfilment of the rule of St. Francis than then prevailed, obtained in 1526 from Pope Clement VII. leave to wear this cap, and to presch anywhere. His example was soon followed by others, and convents of them were established in various parts. They soon spread over Italy, and in 1573 were established in France, and in 1606 in Spain. They followed the Spaniards and Portuguese across the ocean, and the Spannica and I original and the engaged in missionary work in America, Asia, and Africa. The abolition of the monastic system in Germany and France at the close of the last century almost wholly annihilated the Capuchina, and they are fered severely in Spain during the 3rd and 4th decades of this century. At present they are on the increase in all Catholic countries. The Capuchins are enjoined to dress in coarse and mean garments, to go barefooted, and to journey neither on horseback nor in vehicles; to practise the strictest abstinence (though the use of meat and wine is not forbidden); to beg neither mest, nor eggs, nor cheese, but to accept them when offered; to ask for no more than suffices for the day; to gather provisions only for three, or at the most for seven days; to touch no money; to admit as novices persons neither too young nor too weak; to refuse pay for mass; to offices. The Babylonish captivity was brought to a close by the decree of Cyrus, B.C. 536, and the return of a portion of the nation, under Sheshbazzar or Zermortification of the senses and the unter neglect both rabbabel, B.C. 535. What became of the ten tribes is of soul and body which characterized the Capuchius pray in ellence two hours each day; and to observe the ancient strictness in divine worship. The grossest mortification of the senses and the unter neglect both

# Capudan Pasha

gave them great influence over the hearts of the people.

Ref. Herzog's Theological Dictionary.

Capunan Passa, kap'sa-din pa-sha' (Turkish), is the officer who has command of the fleet and the management of all naval affairs in the Ottoman empire. He has also civil jurisdiction over a number of scaports and maritime districts, as well as the Turkish islands of the Archipelago. He is a pasha of three tails, and a member of the divan.

CAPUT, kail put (Lat., the head), in Anat., is applied to that portion of the human body which comprises the skull and face. The skull is distinguished into the following parts:-the vertex, or crown; the sinciput, or fore part of the skull; the occiput, or hind part; the fempora, or temples. The parts of the facies, or face, are the forehead, eyes, nose, &c. (See Face.) The term caput is also applied to,—1. the upper extremity of a long bone, as the humerus; 2. the origin of a muscle; 3. a protuberance resembling a head, as the caput Gallinaginis, a small eminence in the urethra; 4. the beginning of a part; as caput coli, the head of the colon

CAPUT BARONIAL (Lat., the head of the barony), was formerly used to denote the chief seat or castle of a nobleman, where he had his usual residence and held his court.

CAPUT LUPINUM (Lat., wolf's-head), a term formerly applied to an outlawed felon, to denote that any one might slay him that should find him,—that he might be

knocked on the head like a wolf.

CAPUR MORRUUM (Lat., dead head), a term employed by the old chemists to denote the fixed residue of chemical operations after all the volatile matters had been driven off.

CAPUT OBSTIFRUM (Lat., stiff-head), in Med., de-notes wry-neck, an involuntary and fixed inclination of the head towards one of the shoulders.

CAPUT PURGANS (Lat. caput, and purgo, I purge), a name given to a medicine which causes a defluxion from the nose, purging, as it were, the head.

CAPUTIATI, kā-pu-ti-ai-te, in Eccl. Hist., a sect of

religious fanatics which arose in the latter part of the 12th century, in the diocese of Auxerre, and thence a singular kind of cap (capuche), which they wore; whence their name. Their leader, Durand, pretended to be inspired by the Virgin Mary, and declared that their object was to restore peace and liberty upon sarth, by levelling all distinctions, abolishing subordination, and abrogating the magistracy. Hugo, bishop of Auxerre, waged war against them, and succeeded in

putting them down.

CAPPBARA (Hydrochæerus capybara), käp-i'-bă-ră.— This rodent animal is found in the south of America. and in general appearance greatly resembles a small pig. It feeds on vegetables and fish; for which latter purpose it frequents rivers, and swims about in pursuit of its prey with great facility. "They occasionally frequent the islands in the mouth of the Plata, where the water is quite salt, but are far more abundant on the borders of fresh-water lakes and rivers. In the daytime they either lie among the aquatic plants, the daytime they either he among the aquatic plants, or openly feed on the turf-plain. . . . Both the front and side view of their head has quite a ludicrous aspect, from the great depth of their jaw. The animals I saw at Maldonado were very tame: by cautiously walking, I approached within three yards of four old ones. As I approached nearer and nearer, they frequently model their possile which is a lowquently made their peculiar noise, which is a low, sharp grunt, not having much actual sound, but rather arising from the sudden expulsion of air. The only acise I know at all like it is the first hoarse back of a large dog. Having watched the four from almost within wrm's length (and they me) for several minutes, they rushed into the water at full gallop with the greatest impetaceity, and emitted at the same time their bark. After diving a short distance, they came again to the surface, but only just showed the upper part of their heads. When the female is swimming in the when the semale is awimming in the back."—(Darwin.) The flesh of the capybara is esteemed a dainty by the jaguar, which preys largely upon this snimal. The way in which it captures the capybara is very singular. It is said that, leaping to the back of the doomed animal, the jaguar, by a rapid

#### Caraites

movement of the fore-paws, twists its head round, and breaks its neck.

CAR, or CHAR, kar, occurs frequently in the names of places, and teems to be the same as the Celtic caer, which signifies a city.

CARABIDE, kā-rāb'-i-de (Gr. karabos, a beetle), a family of coleopterous insects, comprising several species. The principal characteristics are given as follows:—Anterior tibin without emargination on the inner side; head narrower than the throat; eyes rather prominent; palpi with the terminal joints often compressed, large, and somewhat triangular in shape; mandible simple, moderately long, and rather thick. In general, the members of this family prey upon innently adapted for this purpose, being very firmly encased in a stout covering, enabling them to esarch among the stones, crawing over and under them for their prey without fear of hurt; at the same time they can suffer but little from the attacks of other insects. Some species of the Carabidæ are, it has been ascertained, berbivorous, finding their food principally in the cornfields. In the British Museum may be found a splendid collection of these insects.

CARBINE, or CARBINE. (See CARBINE.)
CARBINERS, kūr-ā-bin-eers' (Fr.), a name formerly
applied to light cavalry employed in the French service. and among the Spaniards, Italians, and Arabs, for skirmishing and outpost duty. Many regiments of English cavalry were once known by this title, but it is now the distinctive appellation of the 6th dragoon

guards.

CARACAL, kā-rā-kāl! (Felis Unracut), some alled the Persian lynx, is found in both the conticalled the nents of Asia and Africa. This animal is the lynx of the ancients. It is about three feet in length, of a pale reddish-brown above, and whitish beneath. It has a small head, although somewhat clongated, and small smin real, annuigh somewhat conflated, and shad ears. In disposition it is fierce and savage, which, combined with great strength, renders it no mean animal. Such qualities, which would, in its wild state, make it rather an inconvenient and troublesome animal to the natives, are turned to good account by employ-ing its services in the chase of other animals and birds, in which pursuits it is said to acquit itself in a highly creditable manner.

CARACARA. (See FALCON.)

Caracole, kar'-a-kol (Fr., a wheeling about), a term applied, in the art of Horsemanship, to the half-turn or semi-round taken by the rider either to the left or right. In the arm, after each discharge, the cavalry make a caracele, in order to pass to the year of the squadron.

CARAITES, kä'-rui-ites, one of the most ancient and most remarkable of the Jewish sects. They kept aloof from the other Jews, and dwelt chiefly in S.-W. Russia, Galicia, Turkey, and Persia. The rabbins make them identical with the Sadducees of the New Testament, or a branch of that sect which separated themselves from the other Jews under the leadership of one Anan, about A.D. 640. The Caraites themselves, however, claim a much higher antiquity, and produce a catalogue of doctors up to the time of Ezra. They are not mentioned by either Josephus or Philo; and hence it seems probable that they were not in existence in the times of these authors. The most likely hypothesis is, that they separated themselves from the Rabbinists about the time of Anan, maintaining the authority of the Word of God, and rejecting the traditions of the elders: hence they received the name of Carain, testualists, nence they received the name of Cardim, textualists, or persons holding by the text of Scripture. They do not, however, reject all tradition, for they have certain interpretations which they call hereditary, and in which they confide. But they give no oredit to the explanations of the Cabbalists, nor to any institutions of the Talmud but such as are conformable to Scripture. Their theology differs from that of the other Jews, chiefly in being purer and more free from supersition. The written Word of God they regard as the only certain rule of faith and practice, and vindicate the right of private judgment in its interpretation. They have many excellent customs, and insist much upon practical piety. They direct their attention chiefly to the law of the Old Testament, to the almost entire neglect of the prophecies; and thus they never

# Carambole

attain to the true spirit of the revelation. They believe In the immortality of the soul; in the resurrection, judgment, heaven and hell, and the other doctrines which the ancient Sadduce's denied. They are simple which the ancient Sadduce's devied. They are simple in their dress and manners; conscientious, peaceful, honest, and true to their word. They mingle but little with other people; but those among whom they live speak very favourably of them. Mr. Oliphant says that "the Caraite merchant enjoys everywhere so high a reputation that throughout the Crimea his word is considered equal to his bond." The number of this sect has been greatly diminished, partly by wars and sect has been greatly diminished, partly by wars and other public calamities, which have befallen the countries in which they were settled. There are at present about 500 in Vilna, 150 in Galicia, 200 in Odessa, and 4,000 in the Crimes. They have also a congregation in Constantinople, one in Jerusalem, one in Alexandria,

and several in Asia Minor and Persia.

CARAMBOLE. (See Avershoot.)
CARAMBLI, ka't-ra-mel (Fr.).—If sugar is melted, and
the heat raised 400° or 420°, the sugar loses two equivalents of water, and becomes a brown, deliquescent,
and nearly tasteless mass. Caramel is often used by cooks and confectioners as a brown colouring matter. The brown colour in brandy and rum is due to a small portion of caramel dissolved in them.

CARAPA, kă-rai-pă (from caraipe, its African name), in Bot., a gen. of tropical plants belonging to the nat. ord. Meliaceæ. C. guineensis, an African species, yields a fatty oil called Kundah or Tallicoonali, which is purgative and anthelmintic. Besides being valuable in medicine, it is well adapted for burning in lamps. It is expressed from the seeds. The bark of the tree has febrifugal properties. C. guianensis, a native of Guiana and the adjacent countries, furnishes similar products; indeed, it is somewhat doubtful whether the species are essentially distinct.

CARAT, or KARAT, kar-at'.—The carat was originally a French weight, and was equal to the twenty-fourth part of a mare or half-pound. It was used for weighpart of a mar or man-penda. Twas used for weight ing gold and jewels, and its weight varied greatly in different countries. In time it fell entirely into disuse, and at the present day the caraft merely signifies the twenty-fourth part of the weight of any piece of gold, or alloy of gold. Thus, if the piece weighted is all gold. it is said to be twenty-four carat gold : if only half of it is gold, it is said to be twelve carat gold; and so on. In the weighing of diamonds the carat is used, and is then equal to 31 grains. The original French carat varied from one ounce to one-third of an ounce.

CABAVAN, kar'-a-van (Persian karwan, a trader), is a name given to a company of merchants, travellers, or pilgrims, who associate together for safety and con-venience, and at stated times traverse the deserts or other dangerous parts of Asia or Africa. In this way commercial intercourse between different countries has been chiefly carried on in these parts from the remotest antiquity. Since the establishment of the Mohammedan religion, travelling has been rendered more common and necessary, a visit to Mecca being enjoined by the Prophet upon all his followers at least once in their lives. Large numbers of the faithful, therefore, assemble in every country where the Mohamucdan faith is established, and proceed in caravans to Mecca. The greater number of those proceeding to that city, however, have trade as well as prayers in view. These caravans are regularly organized by government, and are under the direction of chiefs or agas, who have regardly under them such a suppose of themse access are under the direction of enters of again, and usually under them such a number of troops as is deemed necessary for their protection. The different travellers have their proper place assigned to them in the long line of march, those from the same town or province being usually together. A caravan has some-times several thousand camels, which follow each other in single file, so that it may be several miles in length. Camels are almost uniformly used in preference to the horse or any other saimal, on account of their great patience of fatigue, and their wonderful adaptation for travelling in the desert. The usual arrangement is to

# Carbazotic Acid

Cairo. The former of these is the largest and best regulated, being under the especial protection of the Turkish sultan, and composed of travellers, merchants, and pilgrims from Europe and Asia. The Egyptian caravan, which starts from Cairo, is not so large as the other, and its route is much more dangerous, waster being scarce, and fierce Arab tribes prowling over the country. The Persian canavan from Babylon, and the Moorish caravan from Morocco, have both become Moorish caravan from Morocco, nave very irregular. The great Indian caravan, which very irregular. Besides these great annual caravans, there are numerous others on a smaller scale, and of a more casual nature, con-stantly going in various directions. Merchants and travellers proceeding in the same direction usually wait upon each other until they can form a caravan for mutual protection, when one of their number is generally appointed to direct their movements. Any trader may form a company in order to make a caravan, and he in whose name it is raised is usually considered the chief, unless he appoint another in his place.

CARAVANSARY, Or CARAVANSERA, kar-a-van-sa-re-(Persian karwan, a trader, and serui, a large house); in Eastern countries is a place appointed for receiving and loading caravans; or a kind of inn where caravans rest at night, except that it presents little but shelter, the traveller being obliged to carry all his provisions and necessaries along with him. They are usually erected by the munificence of princes or other great that the provisions is the provision of the present that the provision is the provision of the present that the provision is the torum of the present that the provision is the torum of the present that the provision is the torum of the present that the provision is the torum of the present that the provision is the torum of the present that the provision is the torum of the present that the pres men, and are situated sometimes in the towns and villages, and sometimes at convenient distances along the road. They are usually large square buildings, with a spacious court in the middle; and under the arches or piazzas that surround them there runs a bank raised some feet above the ground, where the mer-chants and travellers take up their lodgings, the beasts of burden being fastened to the foot of the bank. Over or our act being rastened to the foot of the bank. Over the gates there are sometimes little chambers, which the keeper lets out at a very dear rate to such as wish to be private. They are always supplied with water, which is sometimes brought from a great distance. There are some caravanseras where most things can be had for money; and as the profits of these are considerable, they are usually well stored.

CARAVANSEBASKIER, kur'-a-cun-se-ras-keer' (Persiad), the director, steward, or keeper of a caravansers

CARAVEL, or CARVEL, kar'-a-vel (Fr.), a small vessel used in the herring fishery on the coast of France, and usually from twenty-five to thirty tons burden. It is also applied to a light round old-fashioned ship of from 120 to 140 tons, formerly used in Spain and Portugal.

CARAWAY. (See CARUM.) CARBAMIC ACID, kar-bam'-ik (C2H2NO4).-When dry carbonic acid and dry ammoniacal gas are mixed, a white substance results, which was formerly supposed to be anhydrous carbonate of ammonia. Later investigations proved that it was a compound, containing animonia combined with carbonic acid. Carbamic acid forms salts with numerous other bases, which are

acid forms salts with numerous other bases, which are interesting only in a theoretical point of view.

CARBANIDE, kur-bām-ide (CH,NO), a peculiar-compound, formed by the action of ammonia on oblorocarbonic acid. It is said by Natauson to be identical with ures, in which case the equivalent would require to be doubled, C<sub>2</sub>H,N<sub>2</sub>O<sub>2</sub>. (See UREA.) Carbanide may be regarded as carbonic acid with an equivalent of cryam replaced by an equivalent of cryam replaced by an equivalent of a middown. of oxygen, replaced by an equivalent of amidogen.

CARBAZOTIC ACID, OF PICKIC ACID, kar'-bai-zot'-ik CABBAZOTIC ACID, OF FIGHE ACID, ker-par-zor-set, a complex acid, produced by the action of nitric acid on a number of organic substances; such as phenic acid, salicin, phloridzin, silk, indigo, and a number of the resins. It may be prepared in a variety of ways. A large quantity is furnished by heating one part of indigo with eight or ten parts of intrica acid reduced to coarse powder. As soon as the effervescence of nitrio oxide has ceased, the liquor is boiled and nitric acid added from time to time, until no more gas is given off. On cooling, the carbazotic acid crystallizes out in long, pale yellow, brilliant, not angular plates, which contract with a person who has his camels, tents, ser, and the contract with a person who has his camels, tents, are to be washed, redissolved, and recrystallized, vants, &c., and who undertakes to convey the traveller for a given sum. Sometimes 50,000 or 60,000 persons water, forming a liquid of a bright yellow colour. It is times the number was much greater. The principal stead of hops for making bitter taste, and has been used the holy city are those of Damascus and ployed in dyeing silk and wool, to which, in conjunctions

with cream of tarter or alam as a mordant, it gives a flas yellow colour. Carbarotic acid is sometimes employed as a test for potash, with which it forms a bright yellow crystalline precipitate, even in dilute salutions. Carbarotate of potash is anhydrous, and requires 160 parts of water for its solution; the salts

of sods, ammonis, and the earths, are freely soluble.

CARRIDA, kur-bide, a term now employed instead of combinest to denote the union of carbon with a base.

The more important carbides will be found under the

heads of their respective bases.

CARBINE, or CARABINE, kar'-bine (Fr.), a light kind of musket, about three feet or more in length, used by of mustet, shout three test or more in length, usen by light cavalry, the artillery, the yeomany cavalry, and the Trish constabulary. The carabins, or light cavalry, enrolled by Henry II. of France, about 1560, and the carabineers of Louis XIV., in the latter part of the L7th century, were armed with these weapons; and it is uncertain whether these troops derived their name from that of the gun with which they were armed, or whether the gun received its appellation from that of whether the gun received its appellation from that of the troops. The new cavalry carbine made by Mr. Prince is a rifled breech-loader, with a barrel 26 inches long and 733 of an inch in the bore. It weighs 74 lbs. The carbines used by the British cavalry and artillery

are all rifled.

CARROLIC ACID, kar-bol'-ik (Phenic Acid, Hydrate of henyl, Phenole, Hydrated Oxide of Phenyl, Phenylic Alcohol), (C, H, OHO). — Carbolic acid is a very abundant product of the distillation of coal. Laurent obtained carbolic acid from oil of coal-tar by collecting separately those portions which boil between 300° and 400° Fabr. By mixing with this oil a hot saturated solution of hydrate of potash, a white crystalline subsolution of invitate of potasi, a white crystaine substance separates, the supernatant liquid is decanted, and the crystals are dissolved in a small quantity of water. The solution separates into two portions, the denser of which contains carbolate of potash. The potash is abstracted by the addition of hydrochloric acid, and the liquid carbolic acid rises to the surface. The carbolic acid solution is digested with chloride of all the carbolic acid solution is digested with chloride of calcium to remove water, and afterwards exposed to a low temperature. It then crystallizes in long colouriess needles, which must be kept from contact with the atmosphere. Carbolic acid melts at 95°, and boils between 369° and 370°. The slightest trace of moisture tween 389° and 370°. The slightest trace of moisture is sufficient to cause the liquicaction of the crystals. Carbolic acid is but sparingly soluble in water; it is, however, readily dissolved by alcohol, ether, and accide acid. It has a burning taste, and an odour of smoke re-sembling creosote. Its solution does not redden litmus, and leaves a permanent greasy mark on paper if let fall upon it. A splinter of deal dipped in carbolic acid and then into mitric acid becomes dyed blue. Carbolic seid has lately received an important application as a disinfectant and deodorizer, for a full account of which see DEODORIZATION.

CARBON, kur'-bon (Lat. carbo, a coal), -symbol C, CLEBON, kur-bon (Lat. carbo, a coal),—symbol C, equivalent 6, spec, grav. as diamond 3:55, as graphite 1:9 to 2:3,—an elementary non-metallic solid body, very widely diffused through nature. Its purest and rarset form is that of the diamond (see DIAMONN), but in the forms of graphite and mineral charcoal it occurs very abundantly in nearly every part of the world. It also occurs, in combination with oxygen, as carbonic acid, in small quantities in the air, and in the water of most surings. In combination as carbonic the waters of most springs. In combination, as carbonic acid, with lime and magnesis, it occurs, in enormous quantities, as limestone, marble, chalk, dolomita, &c.; whilst, combined with hydrogen, it enters largely into coal, pest, and liquite. From its invariable presence in all organic matter, it has been called the organic in all organic matter, it has been called the organic chemistry "the history of the wanderings of carbon." From entering thus directly into the vegetable and animal creation, carbon may be considered as the most important element; and the pouring out of carbonic said by animals, to serve for the food of vegetables, is one of the many silent chemical operations constantly going on around us. The wonderful provision of Nature by which the carbonic said cast out by animals as a poisonous product is converted into food for the superior of plants, by the action of the sup'rays, has been controlled in the sup'rays. In a beginning the sup's animals as a poisonous product is converted into food for the support of plants, by the action of the sup'rays, has been controlled into the carbon of the sup'rays, has been controlled into the carbon of the sup'rays, has been controlled into the carbon of the sup'rays, has been carbon of the sup'rays, has been controlled into the carbon of the sup'rays, has been carbon of the sup'rays. port of plants, by the action of the sun's rays, has been the admiration of all philosophers and chemists from the days of Lavoisier to the present time. Carbon, as 442

it exists in the form of the diamond, Ca, is fully described under that head; and the same may be said of graphite, CB, which is treated of under the head of BLACK LEAD. ( Charcoal, or amorphous carbon, Cy, exists as ordingry wood charcoal and laupblack, generally combined with incompletely-burned compounds of carbon and hydrogen. Coke and animal charcoal are other forms of carbon. Charcoal is made by inclosing wood billets in un iron retort, to which is adapted closing wood bilets in an iron retors, to which is agapted a tube for conveying the products of combustion to appropriate receivers, and exposing it to a red heat for four or five hours. Where wood is very sbundant, large heaps, covered with powdered charcoal, learned, turf, and earth, are fired and allowed to burn slowly for a mouth or more. Charcoal prepared in this way to receive the terms of the terms is superior to that burnt in retorls. Animal charcoal, or ivory-black, is prepared in cylinders, in a similar manner to that employed for wood charcoal. Carbon, in its amorphous condition, is a black, dense, perfectly in its amorphous condition, is a black, dense, perfectly opaque, insoluble, infusible, incolorous, tasteless body, conducting heat badly and electricity freely. At ordinary temperatures it shows no chemical affinities. This property has been taken advantage of by the aucienta, who used it for ink. The same property has rendered it a common practice to char the inside of tube and casks intended to hold liquids; and posts and piles partially charred are found to last longer under water than when immersed in their natural state. Finely divided charcoal has powerful antisoptic properties, and it is coming into use as a decorrizer to be used for purifying the nir of sewers. Dr. Letheby's late experiments in this direction appear to prove that, by experiments in this direction appear to prove that, by a proper application of charcoal air-filters, the sir in sewers may be rendered wholesome and pure. Charcoal also has the peculiar property of absorbing colouring matter from organic solutions: hence its use as a decolorizer. At high temperatures carbon combines energotically with exygen, and will remove it from great numbers of its combines; hence its use in reducing metallic oxides. Whatever be its source or form, carbon is chemically the same, and, Whatever be ita when burnt in oxygen, forms carbonic said. Boxwood charcoal was found by Saussure to be capable of absorbing gases in the following proportion:-

Hydrogen		times its	volume.
Nitrogen		,,	23
Oxygen	5.13		52
Carbonic neid			10
Sulphuretted bydrogen	pp.	10	2*
Hydrochloric neid	00.	2>	20
Ammoniacal gas	DO.	**	**

It will be seen from the above table that the more unwholesome the gas, the greater the quantity absorbed; a fact which appears to point to charcoal as the great a fact which appears to point to charcoal as the great disinfectant and deoderizer. Indeed, the great success attending the use of carbon for filters, both for air and water, is a proof of its efficiency in this direction. (See Filters.) Carbon unites with several of the elements to form very important compounds. Its inorganic compounds are treated of under Carbonic Acide Carbonic Oxide: Carbon, Chloride of; Carbon, Bislephide of; Carbon, Chron Rightney of (CS) — equipplent 38.

CARBON, BISULPHIDE OF (CS.),—equivalent 38, spec. grav. 1.27, boiling-point 118.5° Fahr. Only one compound of sulphur and carbon is known. It is prepared by heating fragments of charcoal to redness in a retort; into which dip a tube reaching to the bottom of the charcoal. From time to time sulphur is dropped through the tube, which is closed again immediately.
The sulphur and carbon gradually combine, and the bisulphide distils over into the receiver, which is kept cool with ice. It is at first vellow, from excess of sulphur: but by being re-distilled several times, it is obtained in a state of purity. It is a colourless liquid, with an acrid, pungent taste, and a fastid odour. It is nearly nearly the state of the sta with a blue flame, giving off sulphurous and carbonies acid guees. It dissolves sulphur and phosphorus readily, and these elements may be obtained in crystals by slow evaporation of their solutions. Berzelius looks on bisulphide of carbon as a sulphuric acid corresponding to carbonic acid, which is an oxygen acid.

# Carbon, Chloride of

This idea is borne out by the fact, that bisulphide of surbon will unite with several sulphides to form ealts, which are called sulpho-carbonates,—KO·CO<sub>2</sub>, carbonate of potash; KS·OS<sub>2</sub>, sulpho-carbonate of potashism. The solution of phosphorus in bisulphide of carbon is used in electrotyping objects, which age coated with a film or phosphorus by its means, and rendered capable of receiving an immediate metallic covering when plunged into the solution of sulphate of copper. From certain experiments of Berzelius, it is supposed that a protosulphide of carbon exists. A mixture of bisulphide of carbon and solid carbonic acid produces the most intense cold known.

CARBON, CHLORIDE OF .- There are three chlorides of carbon :-

Protochloride of carbon, C<sub>4</sub>Cl<sub>4</sub>. Sesquichloride of carbon, C<sub>4</sub>Cl<sub>5</sub>. Bichloride of carbon, G<sub>2</sub>Cl<sub>4</sub>.

The first compound is formed by passing the vapour of sesquichloride of carbon through a red-hot glass tube tilled with fragments of glass. Chlorine is liberated, and a colourless liquid obtained, which boils at 240° Fahr. It is regarded as a derivative of oleflant gas, C<sub>a</sub>H<sub>4</sub>. The second is formed by acting on Dutch liquid under the influence of solar radiation. It is a volatile crystalline solid, with an aromatic odour resembling camphor. It fases at 320° and boils at 360°. Its specific gravity is 2, and it is soluble in ether and alcohol. There is also a liquid sesquichloride with the formula C<sub>2</sub>Cl<sub>3</sub>, which was obtained by Regnault by passing the vapour of bichloride of carbon through a tube heated to redness. The third, which is often called perchloride of carbon, was obtained by Regnault from wood-spirit and from chloroform by the combined action of chlorine and the sun's rays. Kolbe forms it by passing bisulphide of carbon and oblorine through a red-hot tube. It is a colourless liquid, possessing a peculiar alliaceous edeur, and boiling at 172° Fahr. At -0° Fahr. it becomes a solid of pearly crystalline appearance. Besides these compounds of chlorine and arbon, Faraday obtained a sub-chloride of carbon (C<sub>4</sub>Cl<sub>3</sub>), which formed fine silky crystals, subliming without change by passing the protochloride several times through a red-hot tube.

CARDON, OXYCHLORIDE OF (Chloro-carbonic Acid, Phosgane Gas),—spec. grav. 3.68, symbol COCl.—When equal volumes of chlorine and carbonic acid are exposed.

CARDON, OXXCHLORIDE OF (Chloro-carbonic Acid, Phosgene Gras),—spec. grav. 3-68, symbol COCL.—When equal volumes of chlorine and carbonic acid are exposed to the sun's rays, they gradually combine, and condense into half their volume. Oxychloride of carbon is a suffocating gas, which is decemposed by water into carbonic acid and hydrochloric neid. It may also be formed by passing carbonic oxide through pentachlo-

ride of antimony.

CARBONAEL, Eur-bo-na're (Ital., colliers, or charcoalburners), the name assumed by a large political secret society of Italy, which first emerged from its concealment in 1820. We are still in a great measure ignorant of the nature of this society; for though it has published instructions, catechisms, statutes, and rituals, yet the real spirit of the society and the motives of the leaders are unknown. The stories regarding the great antiquity of this confederation may well be passed over as unworthy of credit. Botta, in his Storia d'Italia, is more likely to be correct in stating that it originated in the republicans who, under Murat's government, equally hating the French and King Ferdinand, fled to the wild recesses of the Abruzzi, where they formed themselves into a secret confederacy under the name of Carbonari. Their leader, Capobianco, is said to have been a man of great rheorical powers. The ritual of the Carbonari was taken from the vocation of charcoal-burning, and their war-cry was "Revenge for the lamb torn by the wolf." Clearing the forest of wolves (opposition to tyrenny) was the basis of their symbols. By this they probably at first meant only deliverance from foreign domiuson; but in later times it denoted freedom from all despotic rule,—antimonarchical and democratic principles having taken possession of them. Among themselves the initiated were styled "good cousins." The place of meeting was called a hut (ba-nacou), the outer district a forest; the interior of the hut was the realita, the place for selling charcoal. The More and the reality of the society it numbered from 24,000 to 30,000 members; and it is said that

# Cerbenie Acid

during the month of March, 1830, no fewer than 68 new members were initiated. The religious and testant nature of the confederacy is evident five rules, one of which declares that "Bucy Carbo has the natural and unationable right to worship has the natural and unationable right to worship." according to his own views and convictions." The bonari seem to have borrowed many of their for from the Freemasons, though they did not spring fro them. After the suppression of the Neapolitan Piedmontese revolution of 1821, the Carbonari through out Italy were declared guilty of high treason, punished as such by the laws. After the restors of the Bourbons, numerous searet societies for themselves in France; and they became united with the Carbonari at Paris in 1820. Soon after this Paris became the head-quarters of Carbonarism, which from this time assumed more of a French character. The initiate were bons cousins; the uninitiated, pagent, or heathens. No written communications were allowed among them, and all intercourse had to be carried on by word of mouth. All treachery was punished by assassination. From the time of its establishment in France to the end of the French and Spanish war, Carbonarism in France was very active. At that time its activity received a check, and it ceased to manifest itself by any open attempts against the government. The society, open attempts against the government. The society, however, continued to hold together till the revolution of 1830; after which many of the most influential of the members attached themselves to the new government, and the society was at length dissolved. In its place, however, the republicans formed themselves into a new society, borrowing the character and forms of the old, and taking the name of the Charbonneris dissections. It was founded for carrying out the winefcratique. It was founded for carrying out the princi-ples laid down by Teste in his Projet d'une Constitution ripublicaine, which were those formerly advocated by Babeuf, and had at its head Buonarotti, a fellow-conspirator of Babeuf. All the operations of this new society centred in Paris, a mode of proceeding which gave offence to the Italians who had joined them, who seceded, and formed themselves into a separate body under the name of "Young Italy." Carbonarism is not known to exist in France at present, the latest trace of it having been found in the south of France in 1841; but it is reported to be still in existence in Italy, or, at least, to have been so up to the recent series of changes.

CARBONIC ACID, kar-bon'-ik (CO<sub>3</sub>),—equivalent 23, spec. grav. 1·529.—Carbonic acid is the product of the combustion of all substances containing earbon. It occurs in combination with metallic oxides in the mineral kingdom, also dissolved in mineral springs. It issues from the earth in volcanic districts, and forms the deadly choke-damp of the coal-mines. It is also a product of respiration, fermentation, and putrefaction, which is nothing more than slow combustion. It is easily prepared by acting on a carbonate, such as chalk or marble, with nitric, sulphuric, or hydrochloric acid, in a gas-generating apparatus. The carbonate of lime is converted into chloride of calcium, and the carbonic acid escapes as gas.

Carbonale of Hydrochloric Chloride of Carbonic Lime. Acid. Calcium. Acid. Water.

Carbonic said is known in the solid, liquid, and gaseous states. By a pressure of thirty atmospheres at \$2° Fahr., it is liquidied, the pressure required decreasing as the temperature gets lower. Liquid earbonic said is colourless, insoluble in water and fatty oils, but mixing in all proportions with ether, sicohol, bisulphide of carbon, naphtha, and turpentine. At \$-94° Fahr. it solidities into a vitreous transparent mass. Solid carbonic acid is best prepared by Thilorier's method, by generating carbonic acid in a condenser until it is liquid, and then allowing it to escape through a stop-cock into the sir. The liquid gas evaporates with such rapidity, that intense cold is produced, and the remainder is converted into snow. It is a bad conductor of heat, and may be handled with impunity, a fim of gaseous carbonic acid always protecting the hand from injury. If pressed upon the skin, a bister is produced similar to that caused by a burn. It is used, in conjunction with ether and simplified of carbon, for producing intense cold. Gaseous carbonic acid is colour.

## Carbonic Oxide

less, possessing slightly seid smell and taste. At ordinary temperatures it dissolves in water in the proportion of bulk for bulk. By pressure, water may be made to take up great quantities of the gas, the same volume being always absorbed, no matter how great the presure, the gas escapes in bubbles. A familiar instance of this occurs in the effervescence of bottled heer or sărated waters. When inhaled, carbonic soid produces death, even when much diluted. A lighted candle is generally used to test an atmosphere suspected to contain carused to test an atmosphere suspected to contain car-bonic scid; but it is found that air that will support compusion will contain sufficient of this gas to cause insensibility and dangerous illness. Carbonic acid produced during respiration may be shown by breathing through a tube into lime-water, which is at once ren-dered cloudy by the formation of carbonate of lime. The ill effects of crowded rooms are owing to the systemic depression produced by small quantities of car-bonic acid. Carbonic acid was formerly called fixed mir, from the fact of its having been discovered solid or fixed constituent in limestone by Dr. Black Though a feeble acid, and easily separable from its combinations, carbonic acid unites with the metallic oxides, forming a very numerous and impor-tant class of salts, the carbonates, descriptions of which will be found under the headings of their bases. The carbonates of the alkalies are soluble in water, the carbonates of the other metallic bases being for the most part insoluble, except the water is highly charged with carbonic acid. Hard water contains carbonate of lime or magnesia, held in solution by the carbonic acid contained in the water : hence, when the gas is dissipated by boiling, the carbonate of lime is precipitated, incrusting the vessel in which it has been boiled. Carbonic acid contains one equivalent of carbon, united with two of oxygen. Its true composition was discovered by Lavoisier, who bestowed

composition was discovered by on it the name it bears.

Carbonic Oxide is produced when carbonic acid is passed over red-hot charcoal; from which it will be seen that this gas is formed during the combustion of almost every organic substance. The first result of a contract of the carbon which is passing combustion is, of course, carbonic acid, which, passing over the red-hot coals or wick, as the case may be parts with an equivalent of its oxygen. The gas, however, is inflamed as fast as it is formed, and reconnected with carbonic acid. It is generally prepared by the decomposition of exalic acid by sulphuric acid. Oxalic acid consists of  $C_2H_3$  united to an equivalent of water, without which it does not appear to be able to exist. The sulphuric acid abstracts this equivalent of water, The surpture and solverstant of equivalent of water, leaving the C<sub>3</sub>H<sub>2</sub> at liberty to separate into CO, carbonic oxide, and CO<sub>2</sub>, carbonic acid. The latter is absorbed by passing the mixed gases through milk of lime. Carbonic oxide gas thus prepared is colourless and inodorous, burning with a blue flame, and giving rise to carbonic acid. It supports betther combustion por respiration, one per cent, mixed with air being sufficient to cause dangerous drowsiness. It is now satisfactorily proved that the coma generally resulting in death produced by the combustion of charcoal in close rooms, is due to the formation of carbonic oxide by the carbonic acid formed during combustion, being It is a neutral body, has no action on itmus-paper, does not combine with acids or bases, and has never been liquefied: it is slightly soluble in water. In metallurgical processes carbonic acid plays an important part by supplying fuel as fast as it is formed.

CARROTTERIOUS SYSTEM, kar-lon-if-e-rus, in Gool., the name given to the great assemblage of fossiliferous strata resting upon the Old Red sandstone, and capped by the Permian series. To this system the great coalfields of the world belong. It consists of alternations of sandstones, shales, clays, limestones, coals, and ironstones, in every degree of admixture and purity, and of every condition of formation,—terrestrial, fresh-water, estuary, and marine. In the strata there have been discovered fossils representing all the great forms of life, with the exception, perhaps, of true dicotyle-donous plants in the vegetable kingdom, and of birds

#### Carbunole

fossil vegetation which marks almost every stratum, and which, in numerous instances, forms thick seams of solid coal. Although this coaly or corbenaceous aspect prevails throughout the whole, it has been found convenient to arrange the system into three groups,—the Lower Coal-measures or Carboniferous Slates, the Mountain or Carboniferous Limestone, and States, the Mountain or Carbonicrous Limited and the Upper or True Coal-measures; or, more minutely, according to the views of most British geologists, into the following series:—I. Upper Coal-measures; 2. Mountain Limestone; and 4. Lower Coal-measures, Other subdivisions have been attempted. according to the local peculiarities of different coal-fields; but it is enough for the purposes of the general reader to know, that all these minor arrangements can be readily co-ordinated with one or other of the above four series. In recapitulating his admirable account of the Carboniferous system, Mr. David Page remarks:— "Looking at the whole succession and alternations of the strata,—the sandstones, clays, shiles, limestones, ironstones, and coal,—and noting their peculiar fossis,—the estuary character of the shells and fishes of the lower and upper groups, and the marine character of the corals, encrinites, shells, and fishes of the middle group, with an excess of terrestrial regetation throughests. group, with an excess of terrestrial regotation throughout,—we are reminded of conditions never before or since exhibited on our globe. The frequent alternations of the strata, and the great extent of our coalfields, indicate the existence of vast estuaries and inland seas, of gigantic rivers and periodical inundations; the numerous coal-seams and bituminous shales clearly bespeak conditions of soil, moisture, and warmth favourable to an exuberant vegetation, and point partly to vegetable drift, and partly to suberroad forests to next-awams and estuarine implest merged forests, to peat-swamps and estuarine juugles; the mountain-limestone, with its marine remains, reminds us of low tropical islands fringed with coral reefs, and lagoons thronged with shell-lish and fishes; the existence of reptiles and insects tells us of air, and sunlight, and river-banks; the vast geographical extent of the system bears evidence of a more equable climate over a large portion of the earth's surface; while the interstratified trap-tuffs, the basaltic outbursts, and the numerous faults and fissures, testify to a period of intense igneous activity—to repeated upheavals of seabottom and submergencies of dry land. . . . The natural conditions under which the system was formed are not more wonderful, however, than the economical importance of its products, —building stone, limestone, marble, fire-clay, alum, copperas, lead, zinc, silver, and above all, iron and coal, are its principal treasures - conferring new wealth and comfort on the country that possesses them, and giving a fresh and permanent impatus to its industry and civilization."— Ref. Page's Admanced Text-book of Geology. Carbuckle, kar-bank-kl (Lat. carbucalus, a little coal), in Surg., is a broad, flat, firm, burning tumour,

usually of considerable size. It occurs most commonly in middle life, and in those who indulge freely in the pleasures of the table. It begins with a hard, painful swelling, of a livid colour, which rapidly enlarges. The pain is severe, and is much increased by pressure; the patient is much depressed, and a general derangement of the system takes place. Vesicles form on the part, which soon open, and discharge a thin viscid fluid, with occasionally sloughed portions of disintegrated tissue. Sometimes these apertures run into each other, and form large openings. The predisposing cause of this disease is a derangement of some of the secretions of the human body, which is to be remedied by purgatives and other medicines suited for each particular case; the system being at the same time supported by tonics and a nourishing dict. This, however, is not enough,—an early and free application of the knife is necessary to the part itself. An incision, usually in the crucial form, throughout the whole extent of the diseased mass evacuates the purnlent formation, and affords an exit for the sloughs when loose. Potassa fusa is also to be freely applied, in order to produce a separation between the healthy and diseased parts, and to prevent injury to the system from absorption of

diseased matter. donous plants in the vegetable kingdom, and of birds | Carryngle, a large gurnet, cut en calochon; i.e. and maximals in the animal kingdom. The most convex on the under side, and concave on the upper, striking peculiarity in the system is the profusion of The light is generally reflected in a flame-like form.

## Carburetted Hydrogen

hence the name. The clear deep-red garnets from Pegu are most highly valued. There are many substi-tutes for garnet, such as the cinnamon-atone, which, when cut en cabockon, deceive even mineralogists. For

The chemical composition of the carbuncle, see Garner.

Carburers, barburers, (See Hadrogen.)

Carburers, karburers, Carburets are now called carbides, the word being more analogous to chloride,

CARDYLE, SULPRATE OF, kar'-bile, ethronic anhydrine, so called by its discoverer Magnus. It is a combination of four equivalents of sulphuric acid with one

of oledant gas. (See ETHIONIC ACID.)
CARCASS, kar-käss (Fr. carcasse), in Mil., a destructive missile discharged from a mortar, like a shell, and designed to set fire to buildings and stores belonging to the enemy. It is a hollow spherical case of iron, perforated with three holes, and filled with combustible matter, which blazes furiously from these apertures, and cannot easily be extinguished. The composition, which resembles in many points the famous Greek fire of the Byzantines, burns for nine or ten minutes, and is lighted by fuses placed in the holes, which ignite at the moment of discharge. The 13-uch carcass contains 18 lbs. of composition, and weighs nearly 2 cwt. They are said to have been first used in Germany about 1670.

Carcass, in Build., a term applied to the bare walls and roof of a house, and the joists of timber running from wall to wall to support the flooring. It is merely the shell of the building, devoid of external decoration, doors, windows, and any internal fittings. The joists that support the floors and ceiling are sometimes called the carcass-flooring, and the frame of the roof that supports the tiles or slates the carcass-roofing.

CARCERULE, kar'-se-rule (Lat. carcer, a prison), in Bot., a superior many-celled fruit, each cell being dry, indehiacent, and one or few-seeded, and all more or less cohering by their united styles to a central axis. The fruit of the common mallow is a good example.

CARDAMINE, kar'-de-mine (from Gr. kardia, heart or courage, on account of its strengthening properties) in Bot., a gen. of plants belonging to the nat. ord Crucifera. C. pratensis, the Cuckoo-flower, or Lady's smock, is an indigenous perennial met with in meadows snock, is an indigenous percental met with in meadows and moist pastures, blossoming in the mouths of April and May, when its flowers, which are flesh-coloured, white, or light purple, present a very pleasing appearance. Formerly the flowers were used medicinally, as a remedy in epillepsy. The leaves are antiscorbutic, and are sometimes enten as watercress.

CARDAMOMS. (See ELETTARIA and AMONUM.) CARD-BOARD, or CARD, kerd-bord (Fr. carte, card; Sax. bord, board), a substance made by pasting together several layers of paper. The number of these layers and the description of paper employed regulate the thickness and quality of the card-board produced. Ordinary card-board is made of fine white paper outside, with several layers of cartridge-paper between. Bristol-board is made altogether of fine white paper. Mill-board is made of coarse brown paper, layers of which are glued together and pressed. It is mostly used by bookbinders. Cards are enamelled by brushing them over with a mixture of china-white and size.

After being rubbed with some fuely-powdered tale, they are polished vigorously with a brush.

CARDIA, kar'di-ā (Gr., the heart), in Anat., is the mane given to the superior opening of the stomach, on

account of its being situated near the heart.

CARDIAC MEDICINES, kar'-di-āk, are cordinls or stomachic and stimulating medicines, which are given

to raise the spirits.

CARDIACEM, kar-di-ai'-se-e (Gr. kardia, the heart), a fam. of bivalve Mollusca. They have a thick, closed, equivalve shell, with the umbones usually bent round, so that the shell, when seen from either extremity, presents a more or less cordate appearance. The hinge-teeth are strong, from one to three in each ange-teem are strong, from one to three in each raive, and there are usually one or two smaller teeth on each side of the hinge. The animal possesses two adductor muscles.—(Dallas's Animal Kingdom.) The Species of this family are very numerous, and greatly vary in size, some of their shells being remarkable for the multiple and dallager of their contraction. the emallness and delicacy of their construction, type of the family is the Cockle. (See Cockle.)

# Cardinal

Carrialets, kar-di-W-ji-U (Gr. kardis, and signs, pain), in Med., denotes pein or an uneasy sensation in the stomach, accompanied with anxiety, a heat magnet less virulent, sometimes attended with oppression of fainting, and frequently with an inclination to wond, or a plentiful discharge of clear lymph-like saliva. (See

or a plentiful discharge of clear tympus many that the matternum, Industries.

Cardinals, kar'-di-add (Lat. cardinals, principal, from cardo, a hinge), is a term used in various connections to denote the chief, principal, or fundamental parts of a thing. Thus, we speak in grammer of the cardinal numbers, in moral philosophy of the cardinal virtues, in cosmography of the cardinal points, and in mateorology of the cardinal winds. It was also the meteorology of the cardinal winds. It was also the name given, under the emperor Theodosius, to the highest officers of the state, as it is in the present day to dignities in the Roman Catholic church.

CAEDINAL, the highest dignity in the Roman Catho-e church next to the pope. The cardinals were at lic church next to the pope. The cardinals were at first only the principal priests or incumbents of the purishes of Rome, which was early divided into parishes. Afterwards it came to be applied to the chief priest of any parish, who was alone allowed to baptize and administer the Eucharist. The title continued to be thus general down to the lith century, when the popes, having grown powerful, formed a college or secret council of ecclesiastics of high rank to assist them in their duties, to whom alone the title of cardinal was soon reserved. At first, the title was confined to ecclesiastics in Rome or its neighbourhood; but afterwards it came to be conferred upon others at a distance, Conradus, archbishop of Mayence, being, it is said, the first who received this honour from Pope Alexander III. In 1160 the cardinals obtained, after much opposition on the part of the other clergy, the exclusive right of choosing the pope, and Innocent IV gave them a rank above the bishops, together with the red hat. Boniface VIII., in the beginning of the 14th red hat. Boniace viii. In the beginning of the century, assigned to them the princely mantle, and Urban VIII. gave them the title of "sminence" instead of "most illustrious." The number of cardinals has varied greatly at different times. In the 12th century they rarely exceeded thirty, and in the 13th there was at one time but seven. In 1516 there were only thirteen, and in 1569 the highest number, seventy-six, was reached. The council of Basel decided that there should be twenty-four; but Sextus V. fixed their number as a seventy. To correspond with the seventy elders of at seventy, to correspond with the seventy elders of Israel. This last has since been adhered to; but the number is seldom full (it was so, however, in 1853, when eight new cardinuls were created), the pope general control of the c rally leaving some vacancies for extraordinary cases. The pope may select cardinals from any country, but with a preference for Italians; and in 1850, of the sixty-seven cardinals, fifty-one were Italians. Their creation occurs first in a secret conclave of cardinals, and is then publicly repeated. The person appointed and is then publicly repeated. The person appointed is solemnly received in a public session of the consistory, and decked with a cardinal's hat. The promotion is completed at the close of the next secret conclave, which the new cardinals attend. In the case of cardinals who cannot attend, the pope dispatches one of his chambermen of honour to carry to them their cap; but they must receive their hat at his own hands. Their dress consists of a surplice with a short hands. Their dress consists of a surplice with a snor-purple mautle, and a small cap, over which they wear the hat, either red or violet, with silk strings and tassels at the end. They have also a ring of sapphire, set in gold, which is worn on the fourth finger. They are divided into three classes, viz., six cardinal bishope, fifty cardinal priests, and fourteen cardinal deacons. In the first class are the bishops of the six suffragan sees of the Roman province; viz., Ostia, Porto, Albano, Tusculum, Sabina, and Præneste: the others generally derived an honorary title from some of the churches of derived an honorary title from some of the cancenes of Rome. In their own college, cardinal bishops rank first, the others according to the date of their appoint-ment. The oldest cardinal bishop residing in Rome is dean of the college of cardinals. This college is the pope's council in all important cases, especially in all ecclesiastical matters, in which he must consult them. Cardinals are alone eligible to the papal chair, and as soon as this becomes vacant, they form a conclare to elect a successor. (See CONCLAVE.) As the pope is both a temporal and an eoclesiastical sovereign, the

415

ardinals occupy civil as well as epiritual offices. The ordinal chamberiess the country of the treasury and inriediction in the court; the cardinal vecretary of state he calinet minister and foreign secretary; the constant vice-chanceller is chief of the chancery; the constant vice-chanceller is chief of the bureau of briefs is chief of the bureau of briefs, recently combined with that of foreign affairs; briefs, recently combined with that of foreign affairs; the cardinal secretary of the interior was first instituted in 1833; the cardinal penitentiary and the cardinal productive are chief of their respective departments. The congregations (which see) are also under the direction of cardinals. The council of cardinals, when casembled under the pope for the discussion of matters.

assumpted under the pope for the discussion of matters affecting the church or the state, is called a consistorm. (See Consistorm.)

CLEDINAL BIRD. (See GROSBEAK.)

CARDINAL NUMBERS, in Gram., are the numbers one, two, three, &c., as distinguished from first, second, third, &c., which are called ordinal numbers, as denoting order.

CARDINAL POINTS, in Cosmography, are the four points of intersection of the horizon with the meridian and the prime vertical circle, or, north, south, east, and west. The cardinal winds are those which blow from the cardinal points. In Astrol., the cardinal points of the heavens, or of a nativity, are the rising and setting of the sun, the zenith, and nadir.

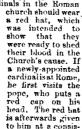

CARDINAL SIGNS, in Astron., are-Aries, Libra, Can-

cer, and Capricorn.

CARDINAL VIRTUES, a term applied in Morals to those virtues which are supposed to comprise all the rest, or to which all the others are subordinate. rest, or to which all the others are supordinate. This distribution of the virtues originated in the ancient Greek philosophy. It is to be found in the teaching of Socrates, as recorded by Xenophon, and was further developed by Plato, who makes them out to be Justice, Temperance, Fortitude, and Prudence. According to Dr. Whewell, this division "fails altogether: ing to Dr. Wheweil, this division "fulls altogether; since the parts are not distinct, and the whole is not complete." He gives in another, which to us seems liable to the same objection; viz., Benevolence, Justice, Truth, Parity, and Order. The Roman Catholic moralists have adopted the ancient division of the cardinal virtues, to which they add what are termed the theological virtues; viz., Faith, Hope, and Charity, making the entire number seven.

Carninal's Har (Lat. cardinal's respectively).

CARDINAL'S HAT (Lat. cardinalis, principal).—In-

CARDINAL'S HAT.

tory, and the proceeding is accompanied by a number of symbolical ceremonies. Except in the case of members of a royal house, the cardinal's hat is always given by the pope's own hands. Some cardinals who have not visited Rome have died without receiving it. The red cap is always sent to a chosen cardinal if absent.

CARDING MACHINE, kar-ding (Du. caurd), a machine in which the fibres of cotton are combed or carded, to disentangle them from each other, and bring them into a proper condition for spinning into cylinders or drums to which strips of leather are fastened, which are perforated with numerous wires regularly arranged. The wires are short and stiff, and the larly arranged. exterior of the cylinder resembles a circular brush. externor of these cylinders are arranged in a strong wooden frame, so that the wires nearly meet, and are set in motion by machinery connected with a steam-engine or water-wheel. The cotton is put into the engine or water-wheel. The cotton is put into the machine at one end, and is rapidly whirled round from sylinder to cylinder until it comes out at the other end in the form of a filmy fleece; this is received on ano-

ther cylinder called the "deffer," from which it is removed by the doffing lattle, and gathered into a marrow make by, passing through a funnel-shaped affecture. It is then ready to be drawn out and spun into yarm and thread. The combs of cards of wire with which the cylinders are coated were formerly made by hand, but they are required in when quantities in Lancashire and the manufacturing districts that they are now made by machinery, invented by Mr. Dyar, of Manchester, in the early part of the present country. part, the wires being also cut in the same machine. These machines for making cards for the cardingengines are very complex and beautiful in construc-

cigines are very complex and beautiful in constitution; each will cut and fix about 500 wires per minute. Cardiosperatum, kar-di-os-per-num (Gr. kardie, heart, sperma, seed, in reference to the shape of the seeds), in Bot., a gen. of plants belonging to the nat. ord. Supindacea. The root of the species C. kaliczcabum is described as disrectic, disphoretic, and spe-rient. The leaves are boiled and esten as a table

vegetable in the Moluccas.

Carottis, kur-di-tis (Gr. kardia, the heart, terminal tile), in Path., denotes inflammation of the heart, It is characterized by pain in the region of the heart, great anxiety, fever, difficulty of breathing, palpitation, cough, irregular pulse, and fainting. It is applied properly to inflammation of the muscular tissue of the heart itself; but this is a form of disease that rarely neart tracit; out this is a form of orease that farely occurs alone, being usually accompanied by pericarditis, or inflammation of the pericarditis, or inflammation of the lining membrane of the heart. The symptoms and treatment in each case are similar. (See Hzart, Diskashs Or.)

Cardon, kur-doon'(Sp. cardon), a garden vegetable, introduced into this country.

introduced into this country about the middle of the 17th century from the south of Europe. It bears a great Europe. It bears a great resemblance to the artichoke, and belongs to the same bo-tanical genus. (See CYNARA.) The tender stalks of the inner leaves, rendered white and crisp by earthing up, are used for stewing, and for soups and salads during the winter. With the florets of the cardoon, called cardo do coulho, the Portuguese for-merly congulated milk for cheese-making.

CARDOON.

CARDS, PLAYING, kards .- Neither the country nor the date of the introduction of playing-cards is known. Possibly they came from the East; for the Chinese and Hindoos have playing-cards that are clearly not of European origin. The manufacture of these articles is a very important one in this country, playing-card makers having been a large and influential body for the last four centuries. The manufacture is carried on under peculiar restrictions. No person is allowed to manufacture them, except in the cities of London and Westminster and Dublin, the manufacture being entirely forbidden in Scotland. They pay a duty of one shilling per pack, which is levied by means of the one staining per pack, which is a government stamp. The aces are printed at Somerset House, on paper furnished by the card-maker, who has to pay for the engraved plate from which they are printed. The ace plates, of which two are necessary, one for the home and the other for the export stamp, cost £30 each. When the aces are required, a requisition is sent in for a ream, containing g.600, and an officer is sent round to every cardinaker, at certain intervals, to seal the pagks containing the sees drawn from the stock. The fluty is collected by the number of seals being counted, the aces not made into cards not being charged for. The stock of sees is counted from time to time, and any deficiency has to be paid for the manufacturer being called on to scoon to for such an irregularity. When playing-cards are exported, the nanufacturer must enter into a heavy bond that the cards will be landed at the port

## Carduelis

specified, to insure a drawback of three halfpence per pound. The income desired from the tax on playing-cards is about £12.000 a year. The cardback used in England for playing-cards is made of thus sheets of Ragiand for playing-cards is made of four sheets of paper. Two strong sheets of cartridgs-paper are first pasted together, dried, and pressed: hees are afterwards covered on each side with a sheet of strong well-sized paper. They are generally painted by means of stencil-plates, with a mixture of water-colour and paste. When painted and dried, they are rubbed with Oastille scap and glazed with a flint. The operation of glazing is tedious and delicate, and causes much waste. The outlines of the court eards and the covarients on the heaver are printed with the ordinary ornaments on the backs are printed with the ordinary letter-printing press. When finished, they are cut up and sorted; the best quality being called "Moguis," the second best "Harrys," and the third "Highlanders," the names being given from the figures on the wrappers. They are then tied in packs, and scaled one wrappers. They are then ned in packs, and sealed by the revenue officer, as before explained. Messrs. De la Rue, of Bunbill Itow, are the first among our English playing-card makers. These gentlemen have, by every mens in their power, tried to render playing-cards works of art, not only on their backs, but on their fronts also. In the former they have succeeded admirably some of the designs being from the hand of mirably, some of the designs being from the hand of Mr. Owen Jones and other eminent artists. tried to reform the public taste by substituting artistic figures of kings and queens for the impossible caricatures in use; but they were compelled to abandon the attempt, after having incurred a very heavy loss. There has been little or no improvement of note in the manufacture of late years, the only important change being the introduction, by Messrs. De la Rue, of a method of printing the cards from metal or wood blocks. A pack of cards exhibited by this firm in 1851, with the backs ornamented in chromo-lithography, cost nearly £1,000. The designs were by Mr. Owen Jones, and consisted of the monograms of the different members of the royal family, wreathed with emblematical flowers. They also exhibited a pack of cards for the use of near-sighted people, the four kinds of pips being printed in four different colours.

CANDUSLIS, Kür-du-o'-lis (from Lat. carduus, a thistie, on account of their love for the seeds of the thistie), a gen. of birds of the Finch tribe. (See

GOLDFINCH, CANARY, &c.)
CARDUUS, kar'-du-us (Lat., a thistle), in Bot., the
Thistle, a gen. of plants belonging to the nat. ord. Composite, consisting of numerous species, some of which are noble-looking flowers. C. benedictus and a few others have been used in medicine as tonics and febrifuges.

CARE OF CARLE SUNDAY, kair, karle, is the second Sunday before Easter, or the fifth Sunday from Shrove-It was formerly a custom in many parts of England to have groy peas steeped and fried in butter, and given away to be esten on this day. These were called carlings. It seems to have arisen from an old Romish custom of eating steeped beans on this day, custom which probably originated from some earlier heathen practice.—Ref. Brand's Popular Antiquities.

CARENING, kār-cen'ing (from Fr. carener, to carean), the process by which a ship is laid down on one side in the water, in such a manner as to expose the other for the purpose of cleaning. It is seldom or ever now used in the British navy, as the copper sheathing with which our vessels are lined prevents, in a great measure, their fouling; and the docks and newly-invented hydraulic lifts by which ships can be raised out of the water render it unnecessary. The Great Eastern, for instance, in 1860 was lifted by the latter means and placed upon a kind of dock called a gridiron in Milford Haven, and was thus enabled to be renaired and cleaned without the dangerous and diffi-

repaired and measure without the dangerous and diffi-cult process of gareening.

CARET, kird-ef (Lat. caree, I want), in Gram., is a mark thus a, used to denote that something has been omitted, and that it is interlined.

# Caries

s, and the plants are som tivated for this purpose on the dyles of These stems, improperly called room, have-medicinally as substitutes for seresperills, name of German sarsaparilla.

Caroanous, kar-gal-dors, is a term applied by the Dutch to a kind of brokers whose business it is to find freights for ships, or ships for freights, and to give notice to merchants of ships that are ready to sail.

CARGO, kar'-go (Span. cargo, a load or bunden), is general name for all the goods and merchandise carri on board a trading vessel. It is sometimes applie on board a trading vessel. It is sometimes applied, also, to the invoice of the goods wherewith the slag is laden. The person often seat with a this is charge of the cargo, and authorized to dispose of it to the best advantage, is called the supercorgo.

CARICA, kai'-re-ka (from being erronsously suppose

to be a native of Caria), in Bob, a gen. of plants be-longing to the nat. ord. Papayaccae. The species are natives of South America and the tropical regions of the old world. The aorid milky juice of O. depitors. the old world. The sarid milky juice of the distants is said to be a deadly poison. The juice of the unripe fruit, and the powdered seeds of C. papaya, are powerful anthelmintics; but the fruit, when cooked, is edible. This plant is said to have the property of rendering meat tender. It is stated that newly-killed meat hung among the leaves soon becomes soft and delicate, and that the flesh of old hogs and old poultry fed on its fruit or leaves is remarkably tendar. leaves are used in some districts as a substitute for scap. The juice is said to be a highly animalized pro-duct, resembling animal albumen in its characters and reactions.

CABICATURE, kår-e-kå-ture' (Ital. caricare, to lead or overcharge), is a representation in which certain parts or peculiarities of an object are exaggerated, but in such a way that the general likeness is preserved, or even made more striking. Though the effect of caricature is generally so produce laughter, yet this idea is not invariably associated with it; for caricature may produce niter or even herror. Caricature in the nice. produce pity, or even horror. Car esture in the piotorial arts occupies the same place that buriesque does in literature. The legitimate objects of the one and of the other are the vices and follies of individuals or of classes, and all disagreeable peculiarities of manner and appearance which arise from these. External deformities, which do not spring from the fault of the persons afflicted, can never he proper subjects of caricature. The ancients employed caricature, as we find from their masks. Among Italian painters, Leonarde da Vinci is a master of this art, representing the quarrelsome, braggart, peevish, gluttonous, clownish, with an exaggerated fidelity. Among the French, Callot, and among the English, Hogarth, stand prominently out in this walk. The Italians have too strong a sense of the beautiful to have a great relish for caricatures, and the Germans are too grave to excel in these sportive productions. The French caricatures are rather exaggerated representations of life than satirical conceptions. The English exhibit a greater approcuother people. Some of the best specimens of carica-ture of any time or nation are to be found in the pages of the hebdomadal Punch.

CARLES, kai'-reez (Lat., rottenness), in Path. Anat. is a disease of the bones analogous to ulceration of the soft parts. It differs from necrosis, in that, in the latter, the bone is destitute of vitality, which is not the case when it is simply carious. Necrosis corresponds to mortification of the soft parts. Caries most frequently attacks the bones of the spine; but it may after any of the bones, especially such as are of a spongy texture, as the carpal or turns al bones, or the heads of the long bones, where they form articulations. The young, or those of a scrofulous habit of body, are most subject to this disease. It sometimes appears spontaneously; at others, as the result of an injury, as a blow or fall. It begins with inflammation, usually about the state of tended with a dull, heavy pain and weakness in the part affected. In course of time an abscess forms, omitted, and that it is interined.

Carax, kai-reks (from Lat. carse, I want, the upper spikes being without seeds), in Bot., a gen. of plants being without seeds), in Bot., a gen. of plants being in the nat. ord. Cyperaces, or Sedge family, of which are British. The creeping stems of C, which are British. The creeping stems of C, arenaria and other species help to bind the sands of affected, and paralysis generally sets in. At the assemble of the spine takes places, arenaria and other species help to bind the sands of affected, and paralysis generally sets in.

ticulation of the hones, the part sularges, the cartilages become affected, and amputation or excision of the joint is aften necessary, in order to save the patient's life. Much may be done in arresting the progress of this disease, at least in its earlier stages. For this purpose, the patient should be strengthened by good air and nourishing diet, at the same time that rest is enjoined: the state of the stomach and bowels should also be attended to. In the local treatment of the disease, blisters, leeches, and issues, are to be employed. The abscesses are best left to nature, unless they are productive of much uneasiness. When they have buret, the exfoliation of the diseased part should have burst, the exceptation of the diseased part should be expedited as much as possible, so that the healthy

portions of the bone may granulate and heal.

CLREKLONS, kir-il'-lons (Fr.), a name given to small massiuments furnished with bells (properly tuned), that are coted upon by finger-keys, like those of a pissoforte, and used for accompanying certain songs where the ringing of church-bells is to be imitated. and where dampers are not used for preventing the continuance of the sound. The steeples of some of the churches in Holland and some parts of the Netherlands are furnished with a large series of bells, tuned accurately to the tones and half-tones of the scale. They are connected at one end by wires with hammers, that strike the bells, and at the other with keys, and pedals for the lower notes of the scale. The persons who play these instruments (called carilloneurs) find it rather hard work, as the carillons are played by striking the keys rather forcibly with the hands and feet. The keys of these instruments are projecting sticks placed far enough apart to enable the performer to strike them with violence and velocity by the two hands edgeways, connected with the bells as those of an organ are with the pipes. The performers on these instruments wear thick leather coverings on the little fingers of each hand, to protect them from the violence of the stroke given. The first and second trebles are played stroke given. The first and second trebles are played with the hands, and the bass with the feet on the pedal keys. Carillon is also the name given to small keyed instruments made to imitate a peal of hand-bells, the tones of which are produced by box hammers striking iron bars of different lengths. Handel used to accompany his air in Milton's "Allegro," "Or let the merry bells ring round," on this instrument.

CARISA, kår-is-sa, in Bot., a gen. of plants belonging to the nat. ord. Apocynacea. The species C. Carandas bears an edible fruit, which is eaten in the East Indies, either alone or with meat, as a substitute for red-currant jelly. The fruits of C. edulis and tomentosa red-current jelly. The frui

OARLINA, kar-li'-na (after the emperor Charlemagne, whose army was cured of the plague by it), in Bot., a gen, of plants belonging to the nat. ord. Composita, and closely allied to the Thistles. C. causits, the Carline thistle, grows on hills and mountains, especially in calcarcous soils, in the middle latitudes of Europe. It was formerly in high repute for the medicinal virtues of its root, which, in large doses, acts as a drastic purgative; but its use is now confined to veterinary practice.

CARLOVINGIANS, kardovin-je-sins, the name of the second dynasty of the Frankish kings which reigned

in France between the years 752 and 987.

CARLUDOVICA, kar-lu-dov'-e-kā (in honour of Charles IV. and Louisa of Spain), in Bot., a gen. of plants of the pat. ord. Pandanuceæ. The unexpanded leaves of C. palmata furnish the material employed in the manufecture of Panama bats.

CARMAGNOLE, kar'-man-yole, the name of a song and dance that originated and became very popular in the time of the first French revolution. It appeared first in the south of France, and is supposed to have re-ceived its name from the town of Carmagoola, in Picd-

noblemen, who were to set as a body-guard to the king in battle.

in battle.

Carmeters, or White Friers, or The Ceners of Our Lady of Mount Carmet, kar mel-ties, a religious order forging one of the four tribes of Mendicants or Beggin; Friers, and deriving both their name and their origin from Mount Carmel. They claim the prophet Bligh as the parent and founder of their community,—an assumption which gave rise to a warm contest between them and the Jesuits about the end of the 17th contern. The order was founded in the 12th the 17th century. The order was founded in the 12th century, by one Berthold, a Calabrian, who came to the Holy Land, and formed a community of hermits on Mount Carmel, at the traditional abode of Elijah. The order afterwards obtained the sanction of the Church, order afterwards obtained the sanction of the Cancon, and a rule from Albert, patriarch of Jerusalem, enjoining poverty, manual labour, living in separate cells, specified prayers, and fastings and silence at certain times. Pressed by the Saracens, they withdrew from Mount Carmel about 1238, and soon spread over Europe, especially Italy, France, Spain, and England. They held their first European general chapter at the monastery of Aylesford, in England, 1245. They had afterwards about forty houses in England and Wales. In 1247 they obtained certain modifications of their rule from Innocent IV., which contributed much to their popularity; and still more so did the adoption of the scapulary, consisting of two stripes of grey cloth, worn one upon the breast and the other upon the back, and fastened together on the shoulders. It was an invention of 1287, and a brotherhood of Scapulary arose, composed of laymen without any monastic vows. The scapulary was revealed by the Virgin, who was said sespinary was revenied by the virgin, who was said to visit purgatory every Saturday, to save all who had at any time borne it, or had died in it. In the 16th century, St. Theresa, a Spanish lady of noble family, undertook the difficult task of reforming this order, which had lost much of its primitive sanctity. with much opposition from the members of the order: but being assisted by Johannes de Santa Crusa, she but being assisted by Johannes de Santa Crusa, she succeeded in dividing the order into two branches:—

1. The Carmetites of the Ancient Observance, or the moderate party, who continued to adhere to their milder rule of discipline; and 2, those of the Strict Observance, or the Bure-footed Carmetites, who went bare-footed, and adopted a much more severe and self-denying course of discipline. There are now four independent bodies or congregations of Carmetites:—

1. Carmetites of the milder rule; 2. Carmetites of Mantus; 3. Bare-footed Carmetites of Spain; and 4. Bare-footed Carmetites of Italy, or of St. Elias, There is also an order of Carmetite nons, which was instituted in France in 1452, and at present are very instituted in France in 1452, and at present are very numerous in Italy.

CAUMEN, kar men (Gr. chairo, I rejoice), a term used among the Latins to signify in a general sense a verse. In a more peculiar sense, they employed it to denote a spell, charm, form of expiation, &c., couched in few words, and placed in a mystic order, on which its efficacy depended. These were generally in verse; but it was also applied to laws, precepts, prayers, and all solemn formula comprised in few words, and arranged in a certain order, though written in prose.

CARMINATURS, kar-min'-i-ins (Lat. carmen, scharm; Fr. carminatif), in Med., is a term applied to certain substances which have the power of dispelling flatuelence, or relieving pain in the stomach and bowels. They belong chiefly to the vegetable kingdom; as, cardamoms, peppermint, ginger, and other aromatic victoriaties.

CARMINE, kar'-mine (Fr. carmin), is the colouring matter of the Coccus cacti, or cochineal insect, and consists of carminic acid united with alumina or oxide of esized its name from the town of Carmagnola, in Piedmont. It was commonly sung and danced at popular further than the success of the preparation of carmine, but festivals, executions, and outbreaks of popular further than the success of the preparation of carmine, but the success of the preparation of carmine and ca

#### Cerminic Acid

CARMINIC ACID, ker-min'.tk.—Mr. Warren De la Rus finds that the colouring matter of cochineal is an acid body, capable of uniting with bases to form: coloured salts and precipitates. He progress it by treating the powdered insect with ethel, to remove the fat, and digesting the insoluble portion in water, decists of lead is precipitated. This must be well washed, decomposed by sulphuretted hydrogen, and the filtered solution evaporated in xuono over sulphuric acid. The colouring matter thus obtained is carminic acid. It is a purple-brown friable mass, soluble in alcohol and water, and alightly emetic. It dissolves unchanged in sulphuric and hydrocolloric scids, but nitric soid decomposes it. Chlorine, iodine, and bromine change its colour to yellow, and the freed alkalies colour the aqueous solution purple. With alum no colour the aqueous solution purple. With alum no precipitate occurs until ammonia is added, when it falls down as a brilliant crimson-lake. The alkaline rans gown as a priment crimson-lage. The significant earths give purple precipitates, and with salts of tin a bright crimson solution is obtained. It resists a temperature of 276.8° (136° C.); but is charred when heated more strongly. Carminic said is a feeble noid. The composition of the substance dried at 248° (120° C.) is represented by C<sub>25</sub>H<sub>14</sub>O<sub>16</sub>.—Ref. Fownes's Chemistry, edited by H. Bence Jones and Professor Hof.

CARMATION. (See DIANTHUS.)
CARWELIAN, kar-ne'-li-ān (Fr. cornaline), in Min.,
a term originally applied to a flesh-coloured calcedony, but now applied to blood-red, yellow, white, brown, and nearly black varieties of this mineral. They consist principally of silics coloured by oxide of iron. This word is frequently written and pronounced corrections. nelian. The finest carnelians are found in Arabia, India, Surinam, and Siberia.

CARNIVAL, kur-ni-rdl (Lat. caro, flesh; vale, fare-well,—i.e. farewell to flesh), the name of a festival observed in Roman Catholic countries, particularly in Italy, immediately before the commencement of Lent, Italy, immediately before the commencement of Lient, beginning on the feast of the Epiphany, or Twelfthday, and ending on Ash-Wednesday. It doubtless arose from the Saturnatia of the ancient Romans, which were orlebrated annually, in the month of December, with all kinds of mirth and freedom, in honour of the golden age, when Saturn governed the world, and when liberty, equality, and happiness prevailed. The Christianized Romans were in this, as in other cases leath to least their pages fastivals, and the Church cases, loath to lose their pagan festivals, and the Church granted her sanction to what she could not very well prevent. The early Christians, it is said, on these days, gave themselves up to voluntary madness, put on masks, exchanged seros, clothed themselves like spectres, and considered all kinds of pleasures allow-able. The rich commenced their festive period at the feast of the Epiphany, or on Three Kings' day; while feast of the Epiphany, or on Three Kings' day; while the middle classes confined themselves to the week immediately preceding Ash-Wednesday, and the poorer classes to the three or four days before Lent. During the last days of the carnival, all kinds of nummery are practised, and freedom of every sort abounds. Home and Venice are now the cities where the carnival is celebrated with the greatest effect; but even in them it is rapidly declining. In Rome the public festivities are confined to the Corso (which is nabout a mile long, but very narrow) and the street ad-joining, and extends over the eight days immediately preceding Ash-Wednesday. The balconies of the houses are crowded with numerous gaily-dressed spectators, and hung with brilliantly-coloured pieces of cotton or silk; while innumerable streamers of the same hues flutter in the breeze. The street below is thronged with carriages filled with gay parties; while crowds of pedes-trians mingle with the vehicles, masked, clad in every variety of costume that fancy can suggest, and playing every imaginable kind of prank. One and all, in the street or on the balconies, engage heartily in pelting each other with flowers, bonbons, and confetti (i.e., small pellets of lime about the size of a pea). Among suan posets or ime about the size of a pea). Among the most usual masks are punchinellos, with enormous noses and protuberant backs and stomachs; harlequins in particoloured vestments, with gwords of last; and pastelones, indulging their usual propensity for thiering by susteining bouquets from the bands of those in the ameliance of the contract of is particoloured vestments, with swords of lath; and pantaioons, indulging their usual propensity for thiering by seatching bouquets from the bands of those in the passing carriages. The festivities do not last the cach side of the neck. It is so balled from the Greek

# Carotid Artery

entire day, but only from about 3 to 5 o'clock, and are each day succeeded by a race by spirited prime without riders. In the evening the windows are illuminated, and the maskers go about with tapers in their hands, every one striving to preserve his own taper and extinguish those of others.

CARRIVORA, kar-nin'-owa (Lat. care, fiesh; core; fierd), a term amplied to all creatures which field

devour), a term applied to all creatures which feed upon flesh. It is definitely applied to that order of the upon ness. It is dennitely applied to that order of the mammalis which preys upon other animals. The forms of this order are very varied. They are furnished with three sorts of teeth, and have nails or claws upon the feet like man and the quadrumans; but they differ from these two orders in not having the thumbs of the satethese two orders in nor naving the tummps of the anter-rior extremity capable of being opposed to the other fingers. The modifications of the molar teeth generally indicate the kind of animal food eaten by carnivors. Some are made for cutting or lacerating, some are serrated, and others are totally or partially tubercu-lated: in the latter case vegetables form a greater or lace reproved to the dist. It all cases the laws of less proportion of the diet. In all cases the jaws of carnivora only open upwards and downwards, and never horizontally. The brain of these animals is ounsiderable in bulk, well marked, but without a third lobe, and does not cover the cerebellum. Of all the senses smelling seems to be in the highest perfection; and as their food does not require much elaboration and digessmelling seems to be in the highest perfection; and astheir food does not require much elaboration and digestion, their intestines are comparatively short. Cuvier
divides the carnivora into four tribes:—1. The Plantigrades, which are distinguished by applying the whole
sole of the foot, especially the hinder one, to the
ground in walking. The bear and badger are instances.

2. The Digitigrades, which have long flexible bodies
and short legs. The ferret and polecat, and the fox, are
instances of the two subdivisions of this tribe. 3. TheFelide, or cats, in which the destructive power is most
highly developed. They are distinguished by the shortround muzzle, the shortened powerful jaw, and the retractile claws, sheathed by means of elastic ligaments,
when the animal is in repose. All the Felides have two
false molars above and two below; the upper flashcutter has three lobes and a blunt heel within; the
lover one has no heel, but has two pointed and entting lobes. They have also one small tuberculated
molar above, without any corresponding molar below.
The tiger is an example of this tribe. 4. The Amphibia;
of which the seal is an example. Many remains of
mammiferous carnivors have been discovered in bone
cayens and osseous breecia. caverns and osseous breccia,

Caro, kd'-ro, a Latin word signifying flesh. It is frequently used in medicine, as well as many of its compounds; as, carnew columna, the fleshy columns or muscular fasciculi within the cavities of the heart; muscular lasciculi within the cavities of the heart; carneus, fleshy, applied to some mucles of the heart; carneus (dim.), a small fleshy substance; carnifornis, having the appearance of flesh; carnicorous, flesh-devouring, applied to animals that live on flesh; carnicology, fleshy.

CAROB BEAN. (See CERATONIA.)
CAROL, kdr-ol (Ital. carola, a song of joy), denoted originally a song sung as an accompaniment to dancing, and afterwards applied to a religious song used in relebration of Christmas. Christmas carols were early in use in the Christian church. According to Tertulian, it was customary for them at their feasts to place in the middle such as were able to sing, and call upon them to praise God in a hymn either out of the Scrip-tures, or of their own invention. Religious songs or ballads in celebration of Christmas are still sung in many parts of England.

CAROLINA PINK. (See SPIGRUIA.)
CAROLINE BOOKs, kur-o-line, the name given to four books drawn up by the bishops of France by order of Charlemagne, to refute decisions of the second council of Nice regarding the worship of images.

CAROLITIC COLUMNS, kar-o-lit-it, columns, the shafts of which are decorated with foliage, flowers, and branches, winding round them in a spiral form, or assuming the shape of wreaths and garlands. The Apprentice's Pillar in Rosslyn chapel is a good example of a carolitic column. The derivation or meaning of the term expelitic is presented.

419

se to sleep, because, if tied or com passed, I cause the along because, if tied or con-passed, the person becomes connatose, and has the appellance of being salesp. The right carotid arises from the atteria innominate, the left from the acrts. The left is thus rather longer than the right, and is in general somewhat smaller. They ascend backwards and outwards into the neck, and, when opposite the os hyoides, each of them divides into the external and in-ternal carotid arteries; the former proceeding to the face and parts without the cranium, the latter to those within. The external carotid afterwards divides into leag branches; vis., the superior thyroid, lingual, luteral, compital, muscular, pharynges ascendens, posterior occipital, muscular, pharynges ascendens, posterior auris, transverse facial, temporal, and internal maxillary. The internal carotid enters the cranium by a semeshat tortuous course, and afterwards separates into four branches,—the ophthalmic artery, and the enterior, posterior, and central arteries of the brain.

Care, kare (Fr. carpe), (Cyprinus Carpio).—This fish is found in most of the lakes and rivers of Europe, and in many places it is cultivated in ponds with great care, although not to a great extent in this country, which is, doubtless, owing to the abundance of salt-water fish. It is said that this fish was introduced into England about the beginning of the 16th century, and it has always been greatly estcemed as a delicate article of food. The carp usually feeds on worms and various insects: this diet, however, in places where this fish is bred, is intermixed with grain, &c. The length of a carp's life is annaing. A century would

seem be about the average; but a healthy fish fish will occasion. ally live to the years, or thereabouts. When it is considered that it is an extraordinarily prolific fish, and that its roe has been known to

turn the scale against the remainder of the carp out of warn the scale against the remanner of the carp out or which it has been taken, it is, perhapa, fortunate that it is so generally popular a diet. The carp usually mea-sures about fifteen inches in length; in warm climates, however, it sometimes nearly reaches three fect. The general colour of the carp is yellowish-olive; the head is large, and the mouth is provided with two beards, one aborter than the other; the scales are large and very distinct.

Very distinct.

Capper, kar'-pel (Gr. karpos, fruit), in Bot., a modified leaf, forming the whole or part of the pistil. When several carpels are present, they may be either distinct from each other, as in the columbine, or combined so as to form one body, as in the poppy. The carpels, taken collectively, constitute the Gynacium, or female

rasen consecurery, constitute the trynactum, or female systems of flowering plants. (See Pisrt.).

\*\*OARPENTER BER, kar'-pen-ter (Xylocopa),—This species belongs to the Apida, or true boss. Its name is derived from the singular manner in which its nest is built. This is generally found in soft decaying wood, and is lined with leaves of a semicircular form cut from plants. It is also known as the Leaf-cutting Bee and It is found in all parts of the world. Upholsterer Bee.

CARPENTER'S RULE, a flat wooden rod used by carpenters for the purpose of measuring work and taking dimensions. It is commonly two feet in length, made of two pieces of boxwood joined by a brass hinge, and divided by means of lines perpendicular to the length of the rule, to show the number of inches, half-inches,

of the rule, to show the number of inches, half-inches, fourths, eighths, and sixteenths of an inch in the entire length. Some rules are graduated in such a way as to sid in calculating the solid content of timber.

Oarraway, kar-pen-tre (Fr. charpenterie), the art of preparing and putting together pieces of timber for building and other purposes. The expression carpentry, strictly speaking, is more particularly applicable to the system of framing pieces of timber together to form the partitions, roofs, and floors of buildings, the trusses and frames of wooden bridges, and the centring er supports on which large arches and the arches of

Dridges are built; as well as the keel, ribs, timbers, and planks forming the built of a ressel, which will be treated under the head SERTEVILDIES, (See SERTEVILEINE.) Although the term carpenter is applied indiscriminately to all who make articles of any kind from wood, yet & must be remembered that rough work requiring great strength and durability in method of construction and materials is put together by the carpenter properly so called, while the interior fittings of a house, such as the stairs, skirting-boards, flooring, doors, windows, &c., requiring greater finish and neatness in execution, are the work of the joiner (see JOINEEY); and pieces of household furniture, particularly those made of the more valuable kinds of wood, come from the hands of the cabinetnaker. The wood, come from the hands of the cabinetmaker. The carpenter should be well acquainted with the proper-ties of different kinds of timber (see Woop), and have a knowledge of the strength and durability of each sort, its capability of bearing great tension and com-pression, and the nower it pressure of maintains the pression, and the power it possesses of resisting the action of various causes that bring about the decay of woodwork. (See MATERIALS, STRENGTH OF.) When a tree is felled for building or other purposes, the trunk is stripped of its bark, and it is left to lie exposed to the nir or the action of waters until it is "generated." trunk is stripped of its bark, and it is left to se expossed to the air or the action of water until it is "seasoned," that is, until it has become hard dry wood, free from sap. At least no wood should be used until it has attained this condition; for many of the discomforts of modern houses arise from the green state of the timber that has been worked up in their construction; and the draughts that come through ill-fitting windowframes, shrunken doors and skirting-boards, and the gaping chinks between the boards of the flooring, are to be principally attributed to the same cause. Unless the timber is thoroughly seasoned, it is also liable to the action of the weather, swelling and fitting far too tightly under the influence of a damp atmosphere, and shrinking, splitting, and warping under the heat of the summer sun. Trunks of trees sent from foreign countries are roughly squared to economize space in the holds of the timber-vessels that bring them to our coast; and in this state they are called "baks." Semetimes they are sawn up and brought over in pieces varying in thickness from 24 to 4 inches. When these pieces are only 7 inches in width, they are called "battens;" if wider, "deals." When the timber is brought in balks, it is sawn up as required into beams or planks by saws hendled by two men in sawpits, or by the action of a circular or band-saw, worked by machinery. (See Saw, Sawmill.) The tools used by a carpenter in the exercise of his art are various. For dividing pieces of wood he has the hand-saw, with a long, thin, elastic blade, every alternate too h of which is turned slightly outwards in contrary directions, and the panel-saw, a smaller tool of similar de-scription. For making incisions in wood to any required depth, the tenon-saw is used,—a small fine blade, with sharp teeth, set in a piece of metal running along the back, to stiffen it and prevent it from bend aing. For cutting out circular pieces, or holes of ary kind, such as keyholes, the keyhole or turning-saw is used, consisting of a narrow stiff blade, decreasing in breadth and thickness, and the teeth becoming finer by degrees towards the end. Smoothness is given to wood by means of tools called planes. A large plane, called a "jack-plane," is used for rough work, and a smaller sort, called a "smoothing-plane," for giving a linish to the surface. Besides these there is a great variety of planes used for cutting grooves in wood and for fashionized different briefs of monthly and the surface. variety of planes used for cutting grooves in wood and for fashioning different kinds of mouldings, which are now generally purchased by builders ready made by machinery. For cutting holes in timber, technically called "mortises," to receive "tanons" or projections from the ends of other pieces of wood that fit into them, strong narrow chisels are used, which are driven into the timber by a mallet. Other chisels of different widths are used for paring and cutting, and "gouges," which are tools resembling chisels brought into a semi-circular form, are used for hellowing out cavities and cutting holes. These are the principal tools of the curcular form, are used for nestowing out cavities and cutting holes. These are the principal tools of the carpenter, with hammers, gimlets, and brad-awis for boring holes for the passage of nails and screws; centrebits for boring holes of various dismisters, con-sisting of short iron boring-tools that are inserted in a socket at the lower end of a curved handle, with a

## Carnet Enights

broad bose at the other end to receive the pressure of the workman's chest when using the instrument; punches for driving the heads of nails below the surpunches for driving the heads of mails below the surface of the wood; rame for smoothing and fashioning places of wood into shapes, such as the twisted shaft so common in Elizabethan furniture; a square for fitting places together, or cutting wood stright angles; a mitre-board for forming the angles of frames; a level for cutting wood at any required angle; a line for marking timber by rubbing it with chalk or charcoal, which medianes a rough imprint by stretching it tightly marking timber by rubbing it with chaik or charcoal, which produces a rough imprint by stretching it tightly from end to end of the required line, and, pulling it from the surface, allowing it to return and strike it amartly; a straight-edge for ascertaining that the surface and edges of a board are perfectly straight and level; a gauge for drawing lines parallel to the edge of asy piece of wood; a scrow-driver, pincers, spoke-shave, compasses and callipers, and a glue-pot. Scrows and nails of all sorts and sizes are used for fastening misces of wood together. but the best sort of nail scrow pieces of wood together; but the best sort of nail seems to be one invented and patented by Mr. Wigzell, late master of the Government School of Design at Exeter, which combines the properties of the mail and screw, and can be driven with the hammer, and withdrawn by means of the pincers, without injury to the nail or wood. The methods used in the construction of the woodwork used in buildings for partitions, roofs, stairwoodwork used in buildings for partitions, roots, stair-cases, &c., will be found under their respective headings. (See Partition, Root, Staircase.) Some of the means used to connect and fit separate pieces of timber together will be found under the heading Joiners.

—Ref. Tredgold's Principles of Carpentry; Nicholson's

Architectural Dictionary.

CARPET KNIGHTS, kur' pet, a term sometimes applied to civilians, or persons of peaceable professions, who, on account of birth, meritorious service, or the like, are raised to the dignity of knighthood. They were are raised to the tigarty of kinglatiood. They were so called because they usually received their honours in the court, kneeling on a carpet, and were thus distinguished from knights created in the camp or on the field of battle.

CARPET MANUFACTURE. (See MANUFACTURE OF

CARPROLOGIA, kar-fo-lo'-je-a (Gr. karphos, the nam of clothes, and lego, I pluck), is the picking of the bedclothes sometimes observed in persons in the de-lirium of a fever, and regarded as a very dangerous symptom.

symptom.

CARPINUS, kar-pi'-nus (Celtic car, wood, pinda, head, the wood being used for the yokes of cattle), in Bot., a gen. of plants belonging to the nat. ord. Corp. Lases, which also includes the oaks, the hazels, the beeches, and the chestnuts. C. betulus, the hornbeam, and C. americanus, yield excellent timber, largely employed for agricultural implements and the cogs of will schools. mill-wheels.

CARPOCHATIANS, kar-po-krai'-shuns, a sect of here carpochartans, kar-po-krau-main, a rece of heat-lies, who sprang up in the 2nd century, and were mend after their founder, Carpocrates, an Alexan-drian. Their doctrines were those of the Gnostics, believing in one supreme original being, from whom all existence has emanated, and to whom it strives to return. The system seems to have been founded in great measure upon the Platonic philosophy, especially the "Phadrus;" and it also beers a close affinity to Buddhism. The finite spirits who rule over the several portions of the earth, they hold, seek to counteract this universal tendency to unity, and from their influence, laws, and arrangements, proceeds all that checks, disturbs, or limits this desire to return into the Supreme Being. The souls of men, imprisoned in corporeal bodies, can only escape by rising above the desires of nature through contemplation. Christ they regarded nature through contemplation. Christ they regarded meraly as a man who had risen to the highest flight of contemplation, and had thus set himself free from the laws of the spirits of this world. Plato, Aristotle, Bocrates, and others, who have risen above the religion of their time, they regarded in the same light, and paid them, also, divine honours. This sect was much press aream, also, cavine monours. This sect was much given to the art of magio, and are said to have been most immoral in their practice, holding a community of wive, and not only sanctioning but inculcating single one of the means of rising superior to the spirits of the means of rising superior to the spirits of is world. This sect, though small, continued to exist down to the 6th century.

# Carriers

Carrus, har-pas (Gr. horpes), is a term in high supplied to the wrist, or that part of the applied sta-tremity between the forearm and the hand. The darpal bones, or bones of the wrist, are eight in num-ber, and are arranged in two rows.— a superior and inferior, each containing four bones. In the superior row, counting from without inwards, are the superior or navioular, the lunar, cuneiform or pyramids, and pisiform bones; and in the inferior, the trapesiums and trapezoid bones, the os magnum, and the inmiform bone.

CARREL OF QUARREL BOLT, kar-rel, the arrow made in cross-bows; a cross-bow. CARRIER PIGEON. (See PIGEON.)

CARREER Figure. (See Propose.)

CARREER, kar-re-ure (Weish cariour; Tr. sharrier, to carry).—Persons carrying goods for hirs,
as masters and owners of ships, hoymen, lightermen, carmen, coachmen, railway companies, and the
like, come under the denomination of commen carriers.
The liabilities and privileges of carriers are treated
of under BALMENT and LIEN. In addition to what will be found under those titles, it may be stated that a common carrier for hire by land or water is answerable, by the custom of the realm, for every less or injury to the goods conveyed, unless occasioned by the act of God or the queen's enemies; and, on the other hand, is bound to receive and convey the goods of every applicant who is ready to pay the price of carriage, provided he has room for them, and his liability is capable of being varied by a special contract (if any should happen to be made) relative to the terms on which goods are to be carried on any particular occasion. Accordingly, it was competent to him at common law, by a public notice of the terms on which he deals (as by a notice that he will not be liable for goods beyond a certain value, unless booked as such; and paid for at a higher rate), to limit the measure of the responsibility; for upon proof, direct or presumptive, that such notice came to the knowledge of the customer before the goods were sent, the law would suppose a special contract between the parties conformable to the terms of the notice, though it still held the carrier responsible for negligence or wilful misconduct; and such is still the state of the law with respect to carriers for hire by water. (See 8 & 9 Vict. c. 42, enabling canal companies to become common carriers.) But, as to those by land, it is now provided by 11 Geo.
IV. & 1 Will. IV. c. 98, that no public notice shall limit
or in anywise affect their liability at common law for or in anywise affect their liability at common law for any goods in respect whereof they may not be entitled to the benefit of that act (sec. 4). On the other hand, however, the same statute (reciting that by reason of the practice of sending money, bills, notes, jewellery, and other articles of great value in a small compass, the responsibility of carriers by land for hire had been greatly increased) enacts for their benefit that no such carrier shall be liable for loss or injury to certain enumerated articles of the general description men-tioned in the recital (when the aggregate value shall exceed £10), unless, at the time of delivery to the carrier, the value and nature shall have been declared, and such increased charge paid thereon as by a legible notice affixed in the office shall have been previously advertised to the public; but if no such notice shall have been affixed, or if the carrier shall refuse (when required) to give a receipt acknowledging the parcel to be insured, he is not to be entitled to the benefit of the act, and remains liable as at common law (sees. 1, 2, 3). It has been held, however, that where the carrier has complied with the act, and the customer has not, the former is not liable to the latter even for gross negligence. It is also provided that nothing in the act contained shall affect any express special contract between the carrier and customer, or protect the carrier in any case from loss arising from the felopious acts of any servant in his employ, or protect any such servant from liability for loss occasioned by his own servant from liability for loss occasioned by his own personal neglect or misconduct (sees. 6, 8). In the oparticular case of a conveyance by sea, it is to be observed that the liability of the shipowner (though he is, in point of law, a common carrier, if the ship be ordinarily hired to carry goods) does not sanally rest on the common-law role, but on the special contract created between the parties by the bill of lading; and that a bill of lading; and that a bill of lading, in its most ordinary form, con-

# Carronades

Carthamia

tains an exception of the act of God, the act of the queen's enounce, fire, and all perils of the seas. By various acts of partitions at, also, shipowners are ex-empted from Barrity for losses arrains from any act recommend to permanent, sans, ampowers are ex-empted from unblitty for losses arising from my act done without their fault or privity beyond the value of the sinp and freight; and are, moreover, protected from those which occur by the breaking out of a fire on board the vessel. (See Ballurat, Bill or Lading,

CARROTADES, kin-ros.cids, short cast-iron guns, arting a changer to receive the powder similar to a mortar, and attached to the carriage by a bolt, which are through a large iron eye or loop underneath the patiest shrough a large ron eye or loop undernesse use that, instead of working on trunnions, as large pieces of ordinance generally do. They derive their name from the Carron foundry, near Falkirk, where this kind of casnon was first cast. As their range is limited in citient, the carronades were more particularly useful in sea fights when the contending vessels came to close quarters, or in breaching ramparts when they were placed pretty near the face of the work; but at short distances they threw shot and shell as effectively as larger guns, and they had this advantage, that they were much lighter, and could be handled by fewer men than long pieces of the same calibre. In consequence of the improvements that have lately taken place in gunvery, carronades are now but little used.

CARROT. (See DAVCUR.)

(CARROTSAI, kin-row-zill (Ital. carrosello, dim. of carro, a chariot), is, properly, a course or contest of chariots and horses, but generally applied to a magnificent entertainment given by princes or other great personages on occasions of public rejoicing, and consisting in a cavalcade of persons richly dressed and equipped, after the manner of ancient cavaliers, who met in some public place to practise jousts, tourna-ments, and the like. Carrousals took the place of the earlier tournaments, and were common in all the courts of Europe down to the 18th century.

CARRUCATE, kard-ra-kuit (Lat. carrucata), in the ancient laws of England, denoted a plough of land, or as much as one team could plough in a year. The ns much as one team could plough in a year. The contents of a carrucate are very variously stated, and indeed, it seems to have varied at different times and in different parts. In the Domesday survey, the hide and carrucate appear to be the same. In the early part of the reign of Richard I., the carrucate is said to have been activated at 60 areas for the same. have been estimated at 60 acres, and to have been afterwards fixed at 100. In the time of Edward I., it appears to have been more than once estimated at 199 acres; and in the 23rd of Edward III., a carrueste of land in Burcester contained 112 acres, and in Middleton 150.

CLRTE BLEFORE, kart blaunsh (Fr., white card), is paper containing nothing but the signature and, it may be, the seal of the party who grants it, in order that the party receiving it may fill it up or insert such conditions is it as he pleases. Generally, the term is used to express unlimited authority delegated by one person to another to set as he may think best. Thus, a representative is said to have received carte blanche from his sovereign if he has unlimited power to deal with those to whom he is accredited.

CARTEL, kar'-tel (Fr. cartel; Sp. cartello), a term a terms, kar-ter (fr. carret; sp. carretto), a term applied to an agreement between two states that are at war, for an exchange of priseners. It is also a challenge to fight a duel. Ships that are used to convey exchanged prisoners, or to take messages from one hostile power to another, are called cartel ships, or by the French bdsiments parliamentaires. To such ships one

the Franch bettiments parliamentaires. To such ships one gius only is allowed for the purpose of making signals.
Cartesian Frincosorar, kar-te-se-din, is that system of philosophy which owes its origin to Descartes (1596—1850), who is entitled the father of modern philosophy. He endeavoured to constitute philosophy a demonstrable science, founded on the principles of pure ranjonalism, and was to philosophy on the continuent whee Bacon was to it in England. Unable to find any firm ground in any of the prevailing systems, distracted by doubtf, mistrusting the evidences of his senses or the conclusions of his understanding, he determined to reconstruct his knowledge, to believe nothing but upon the shearest evidence of reason, and to examine the remines of every conclusion. He pushed his sceptions of six that he came to doubt everything but his iciem so far that he came to doubt everything but his 452

own existence. It appeared to him that doubts might own existence. It appeared to him that doubte might reasonably be enfortained about everything but his own cristence; to doubt the existence of that which thinks and doubts, appeared to him to be an abstractly. Setting out, herefore, from his well-known postulation. Copita, sayo sum (I think, therefore I am), he resolved to admit nothing which could not be deduced from it by a chain of logical reasoning. He did not attempt, as some philosophers have held, to prove his own existence in this way; he merely regarded it as the valvining about which there could not possibly be any doubt. His next step was to lay down certain rules for the detection of truth. These were 1—1. Never to accept anything as true but what is so evidently, so accept anything as true but what is so evidently, so that there can be no reason to doubt it. 2. To divide every question into as many separate questions as pos-sible, that, each part being more easily conceived, the whole may be more intelligible. 3. To conduct the examination with order, beginning with the most sim-ple, and rising by little and little to the most samplex; and 4. to make such exact calculations, and such cir cumspections as to be certain that nothing essential has been omitted. Consciousness being the ground of all certainty, everything of which we are clearly and distinctly conscious, must be true, and everything which we clearly and distinctly conceive, exists, if the idea of it involves existence. The method of ressoning lees of it involves elistonee. An interest was, in his view, the mathematical. "Those long chains of reasoning," he says, "all simple and easy, which geometers use to arrive at their most difficult demonstrations, suggested to me that all things which came within human knowledge, must follow each other in a similar chain; and that, provided we abstain from admitting anything as true which is not so, and that we always preserve in them the order necessary to deduce on from the other, there can be mone so remote to which we cannot finally attain, nor so obscure but that we may discover them." To prove the existence of God was the first application of his method. This conscious-ness of mine is finite and imperfect; but influity and perfection are involved in these ideas, and innate perfection are involved in these ideas, and innate in the mind; therefore an infinite and perfect being must exist. The fundamental attribute of matter is extension, of mind is thought. The soul, whose nature consists in thought, is simple in its essence, or, in other words, purely immaterial, but intimately connected with the body. The pineni gland he supposed may be its seat. From the immateriality of the soul he deduced its immortality; but lest he should be obliged to extend the same recognise to where minute. In recognition, the same recognise to where minutes he recognised the same recognise to where minutes he recognised. to extend the same properties to other animals, he pronounced them to be living machines. The soul is free because it thinks itself so, and in this very freedom consists its liability to error. He made a distinction between sists its insulity to error. He made a unsumption between the passive impressions and active decisions of the soul. He constituted three classes of ideas: advantitious, or those which we naturally acquire; those which we create; and innute, or those which are born with us. He accounts for the communion existing between soul and body by his doctrine of Assistance,—the assistance or co-operation of deity. Notwithstanding the many defects of the Cartesian philosophy, its confusion in some parts and contradictions in others, and a want of conclusiveness in many of its inferences, it swakened men to independent thought, and impelled them to inrestigate the fundamental principles of philosophy.—

Ref. "Enfield"s, Lewes's, and Tenneman's Ristories of Philosophy; D. Stewart's Dissortation on the Progress of Philosophy.

CARTHAMIN, kur'-thil-min, the red dystar principle of the safflower, or Carthamus timeterius. It is obtained by digesting safflower in weak social safe to remove the yellow dysatuff. The washed dye is digested in a solution of carbonate of sods, and a skelar of sotton is placed in the liquid, and lemon-juice or static said is added. The colouring matter is removed by the sotton, from which it is washed, redissolved in carbonate of sodu, and reprecipitated with citric acid. When dry, carthamin is a red pulverniest substance, metallic green when viewed in the mass, but purplish-red when seen in thin layers. Safflower was formerly much used as a dy, partionistly in the form of pink asserts, for dyeing silk stockings; but its ingitireness is a great objection to its use. Selliower is largely used in the

manufacture of rouge for the tollet.

Discussion, Low-thiness (from the Arab, quorious, o paint), in Mor., a gen. of plants belonging to the at. and. Compacter. The most important apacies is in the contract the sufficient, or hansed earlier. The sects of this yield a posteriful plak dye, and are constitutes used to electronists hay suffice. in oil

count out. Insurance, for the sides, a religious order unded by one Brano, a very learned man and properly ability of a philosophy in Peris, about 1080. They are so that from the desert of Chartreuse, near Grenoble, place of their first institution, and are remarkable the austerity of their rules. The members cannot or the austerity of their rules for the statemy of their rules. The memoria camericars their cells not speak to any one without the permission of their superior. Their beds are of straw, with a covering of felt or course cloth. They wear listinglish shirts, white cassooks, and over these black chasts. In their refectory they are to keep their eyes on the mest, their hands on the table, their attention on the reader, and their heart fixed on God They are not allowed animal food, must fast every Friday, except a annul allowance of bread and water, and observe an almost perpetual silence. When allowed to discourse, they are to do so modestly, not m a whisper, ner yet in a loud or contentious manner They con-less to the prior every Saturday The convents of this The convents of this order are generally very beautiful, that of Napics, though small, is most magnificent, and richly ornamented. The Carthusians first settled in Lingland in 1130, and had monasteries in various parts of the country. There was one estal hand in I indoi where the Charterhouse (a corruption of the original term) how stands

CARTILAGE, ker'-ti let (Lat cartilago), in Anat, is a white, firm, elastic substance, intermediate between bone and ligament, and commonly known by the name of gradie Cartilages are divided by anatomists into— 1, articular or obducent, covering the surface of the bones, which form movable joints, 2 inter articular, which are situated between the ends of bones forming artifulations; and 3 connecting curtilage, which unites one bone with another. In some cives, cartilage oc cars unconnected with hone, as in the larynx and tra-ches. In early life, cartilage in various parts occupies the place of bone, and becomes afterwards cashied The physical properties of cartilage—its firmness, clasticity, and powers of resistance—render it specially litted for the purposes which it serves, facilitating the

notions of bones or connect ng them together CARTILAGINOUS FIRMES, Lar-to by 4-nus, are fishes the skeletons of which are destrute of bony fibre In some cases they would almost appear to form the con-meeting link between the vertebrate and invertebrate animals. The skeleton of the lancelets, for example, is merely fudimentary, it simply consists of a slight transparent flexible dorsal column. The dorsal column transparent flexible dorsal column. The dorsal column of the lamprey also presents a similar appearance. The captire of the backbone of the sturgect is a column of sartlinge, and the vertebrae of sharks consist of hollow cones, which have their cups filled up with the remains of a gelatinous cord. Great fleationty is the result of this arrangement. In many of the more laighly organized cartilaginous fishes, several vertebrae are joined together in one piece, and the shall is formed without sutures, although the shape corresponds with that of other fishes. Cuvier placed cartilaginous flakes with the batrachian restiles in his class 4 months of the same control of the same cartilaginous flakes with the batrachian restiles in his class 4 months of the same cartilaginous capacity. shes with the batrachian reptiles in his class Amphibia Naturalets are now, however, unanimous in placing them in the class of fishes. The heterocercal tail is ruem in the class of manes. The neterocercal tail is one of the most remarkable characteristics of all classes of this had of fish. The vertebral column is prolonged into the upper portion of the caudal fin, and the lower out is given off beneath. Similar tails are to be ob-served in the fossil fishes of the Ol I Red Sandstone

ttion of the Soriga and the d n, however, of factors may be excided by per," which is now m may extent a drawing paper drawing-papes," which as now mange gar, as contanuous sheet of greet width and a length. CARCERDGE PAPER is a strongly-manufacture by this name, having he which is called by this name, having to the first instance, for soldiers unstained surface causes it to be extensively used architects, and engineers for their drawing three kinds of this paper,—Common Carriers, and Double Rugineers Cartridge, and Double Rugineers Cartridge, and Double Rugineers Cartridge, and Double Rugineers Cartridge, and Double Rugineers.

ginally found there), in Bot, a gen. of plants ing to the nat. ord. Umbellifera. The species is the common caraway, a native of most Burope. It is largely cultivated in Essex for a commonly called seeds, which have a pleasant odour and a warm aromatic taste, owing to the presence of about five per cent, of volatile oil. They are much used in confectionery and for flavouring cakes. The oil, obtained by distilling the fruits with water, is

on, obtained by distance the fruits wash water, as used as a corrective adjunct in medicine.

Caruncia, kar'-un-k! (Lat. caruncula, dim. of caro, flesh), in Anat, is used to denote a small place of flesh, or a little fleshy excrescence; hence the caruncula lachymalis, a small fleshy glandiform body, situated on the inner angle of each eye.

Stuated on the inner angle of each eye.

CARUS, kill-rax (Gr. kara, the head), in Med., denotes profound sleep, or lethargy (which see).

CARUING, karl-ring (Sax. cearfun, to carre), a term more particularly applied to the production of figures.

fruit, flowers, and ornamental work, from pieces of wood or vivery, by cutting the same into the desired shape by means of chisels, gouges, saws, and files of the necessary forms. The art of carving is called "sculpture" when stone is the material employed, and "chasing" when the work is executed in metal. The ancient sculptors of Greece, and those of Byzantium in later times, excelled in carving in ivery; and magnificent cups, crucilizes, and other works of ore, were produced in this material in Italy and the Low Countries between 1200 and 1600. The Hindoos and Countries between 1200 and 1600. The Hindoos, and Chinese are famous for their delicate and chabrate carriog in irory to this day. Magnificent specimens of wood-carving are to be found in the majority of eathedrals and churches in the Gothic style of architecture erected during the aniddle ages in England and on the Continent; while Windsor Castle, Hampton Court, St. Paul's Cathedral, and many of the residences of the nchiltre are enriched with work produced by of the nobility, are enriched with work produced by the chisel of Crinling Gibbons, a carver of considerable the cliner of extining chooses, a carrer of consideraous repute, who excelled in the production of fruit and flowers, and flourished between 1670 and 1721. This art has been revived to a great extent in the present day; and some beautiful carrying in wood may be seen at the New Palace at Westmanster, mostly executed at the New Falace at Westmanster, mostsy execution by machinery contrived for the purpose, as well as at St. Michael's Church, Cornhill, and the chapel of Jesus College, Cambridge. The Swiss are extremely ingenious in carving animals in acit wood; apprited ingenious in carving animals in soft wood, sparase affigures being produced by comparatively few strokes of the tools employed. A very effective imitation of carving in oak and dark wood is made in gutta-percha and leather, which is softened and present in modifials prepared for the purpose. The Keuliwork sideboard, and one known as Stevens's sideboard, made by Mr. John Stevens, of Taunton, the former of which was shown at the Exhibition of 1851, and the latter in that 1862 may he outed as affording good aneximens of of 1862, may be cited as affording good specimens of modern artistic skill in carving in wood. Within the last twenty years the application of machinery to the carving of wood has been brought to some degree of perfection. A pattern of the work to be carved in in wire network. In the third kind—the Green Cartidge, which is the strongest of all, the eavelope is formed of a stronger wire network. The annexed figure shows a longitudinal section of one of the many kinds of breech-loading cartridges for sporting or stort gues. A is a brass pin, which, on being struck by the banders of the gun, is driven down upon the percussion—cap (b), whereby the gaupowder (c) is exploded, and the shot (f) propulled from the gun. The cart of the work can only be executed by the machine and the first instance, prepared by the machine upon seature of stance. The work can only be executed by the machine a cat of forwardness, after which the machine to a tate of forwardness, after which it must be finished by hind. In 1848, Mr. Pratt invented a cartridge is closed up to a being struck the principle of the interest of the gave to the Institute of British Architects. His machine combined the purious production, and the cartridge is closed up by a brass capsule,

following description from the displate Oydepastic.—
"The material in which the design is to be carred in fired on a table, which turns on a source. The table, acting in the manner of a contrabit, is attached to an arm, also working on a centre, and is made to recover with great valouity. Guided by a pattern of cest iron, the tool, by a double movement of the arm and the table, can be made to pass through any combinations of curves, drilling out the material as it passes over it. The lines of the design are determined by the iron pattern, and the depth and form of the sinking by the shape and position of the tool; and if a double moulding is required, two patterns and two tools, and a double operation, are necessary. The tool and its position at the end of the arm being once adapted to the section of the moulding to be produced, the rest purely mechanical. The tool revolves three thousand times a minute, and the wood is cut away in the form times winne, and the wood is cut away in the form of very fine fragments, like aswdnet, laving a smooth surface behind it." The best-contrived and most extensively used carving-machine is that invented and patented by Mr. Jordan in 1845. This machine has patented by Mr. Jordan in 1840. This macnine has since that date been constantly employed in carving the desorations for the interior of the Houses of Parliament. Mr. T. B. Jordan, the engineer, in describing his invention in Uro's Dictionary of Arts, Managinotures, and Mines, thus prefaces his explanation of the working of his machine:—"Its principle of action and its construction are widely different from that above described (Mr. Irving's), and is is capable of copying any carved design which can be produced, so far as that is possible by revolving tools; the smoothness of surface and sharpness of finish is neither possible nor desirable, because a keen edge, guided by a practised hand, will not only produce a better finish, but it will accomplish this part of the work at less cost. The only object is sing machinery is to lessen the cost of products or to save time; and in approaching towards the time of a piece of carring, there is a time when full a progress of the work on the machine would be more appears to that the ball it by hand. This arises from the necessity of assing smaller tools towards the finish of the work, to prenetrate into its sharp recesses, and the necessarily tion and its construction are widely different from that penetrate into its sharp recesses, and the necessarily now rate at which these cut away the material; it is consequently a matter of commercial speculation how far it is desirable to finish on the machine, and when but it into the hands of the artist, so as to se-bure the greatest economy. This depends in a great measure upon the hardness of the material;—rosewood, chony, box, ivory, and statuary marble should be wrought very nearly to a finish; but lime, deal, and other soft woods should only be roughly pointed." The exrangements of Mr. Jordan's improved machine, the details of which are delineated at figs. 1, 2, 3, on Plates XXVII, and XXVIII., may now be described:— Fig. 1 is a plan, fig. 2 a front elevation, fig. 3 a side elevation. The same letters of reference are used to denote the same parts in every drawing—A B C D is a cast-tron frame, forming the bed of the machine; the upper portion of the sides A B and C D is planed perfectly straight, emouth, and parallel, and they serve as a railway for the wheels (E, F, G, H) to run ou. These wheels are mounted between centres, which are fixed to the frame I J K L, and are so adjusted us to insure the steady motion of the frame in a horias to insure the steady motion of the frame in a horizontal plane, and in the direction of the lower rails only. If N O P is the floating-table, or chuck, of the machine, to which the work and patterns are attached; and it is furnished with wheels, which roll on the upper edges of the frame I J K L, the like procaution of nice adjustment being observed. It will readily be seen that this arrangement gives the workman the morning the work about in

from 5,000 to 7,000 revolutions of the cutters per minute; Q R is the treadle, which is managed by the workman's fact, and seepes to raise and depress the cutter; its connection with the horizontal bar cerry-ing the pulleys (13 and 14) is this shown in the draw-ings. The weights (5, 8) are a counterpoise to that of the side and parts connected with 5, which say the cased at pleasure, according to the number of manthe slide and parts connected with it, which are his varied at pleasure, seconding to the number of man-drils in use; 15 is a ston-acrew, which vegulates the range of the slide to which it is fixed, so that is mannot turn in its bearings. It peases through a free hole is the bracket (16), which serves as a stop to the looking nuts (17 and 18), and these may be fixed on any part of the acrew, so as to determine the distance through which the slide shall move. In very large much is requisite to introduce some mechanical arrange for giving the workmen more command over the ments of the floating-table; and I find that sh obvious that several modifications of the rest and pinion, or the screw, may be used with nearly the same The arrangement shown in the drawings of effect. The attrangement snown is the unavings con-sists of the steering-wheel (U) and its axis, which passes across the centre of the lower rolling-frame, and is furnished with a drum of three or four inches diameter, about which is coiled the centre position of the wire line V V, while its ends are fixed to were the (W, W), which pass through sockets case on the feat-ing-table; and consequently turning the steering wheel to the right or left will give a corresponding motion to to the right or left will give a corresponding motion to the work just inside the steering-wheel; and on the same axis there is a small cogged wheel (X), which serves to fix the axle, and, consequently, to stop the motion from right to left, whenever the detent (Y) is dropped into its cogs. In some cases, as where the floating-table and work are very heavy, it may be desirable to move the table by the steam power, as in the following manner:—Z Z is an endless band passing over pulleys fixed to the bed of the machine, to which allow motion is communicated from the float motion is communicated from the float machine. a slow motion is communicated from the first mover at a a; it passes through the jaws of a clamp (b), which is so arranged as to allow both sides of the hand to pass freely when the handle of it is in a central position, and to clamp the frame to the right or left portion of the band when in either of those positions. Of course the result of this is, that when the left portion is clamped, motion is given to the work in that direction in which it is travelling, and the opposite direction is obtained by reversing the clamp; but the band itself always travels in the same direction. The this facility of the clamp is the clamp in the clamp is the clamp. always travels in the same direction. Fig. 4 is a front elevation of a part of the machine, with the additions requisite for cutting on the round, with a side plevation of the headstocks and turning-plate, &c. A. B repre-sent headstocks, which are fixed to the floating table for the purpose of supporting the work between centres, in order that it may be carved on every side: several pairs of these may be fixed on the table at one time, dependent on the number of pieces it is intended to cut. The mandril of A is provided with a wheel (C) having a screw cut in its edge suited to the edge of the screw d, which, when in use, is placed across one and of the floating-table in the bearings e, e, and is edjusted to gear with the wheels of all the front headstocks in use; the back headstocks (b) are fixed to the table exactly opposite the front ones, and are used for supporting the other ends of the pieces of work and pat-tern. When the table is thus fitted with its headstocks and work, supported between centres, any motion given to the wheel M, which is the head of the large screw, will move all the pieces of the work through screw, will move all the pieces of the work through a centre angle, and present another face of it to the cutters; and if this turning of the screw is continued from the screw is continued. seen that this arrangement gives the workman the power of moving the work about in every possible direction in a horizontal plane. Other details in the construction of this part will be better understood after the whole irreuniference would eventually be careed. At D there is a cogged wheel fixed on the strew d, with a feet the supports for the vertical slide and other parts connected with the cutting and tracing apparatus; 6, 6 is the slide; and 7, 8 s bar cast on the slide, which has a T groove through its whole length, and to which has a T groove through its whole length, and to which has a T groove through its whole length, and to which has a T groove through its whole length, and to which has a T groove through its whole length, and to which has a T groove through its whole length, and to which has a T groove through its whole length, and to which has a T groove through its whole length, and to which has a T groove through its whole length, and to which the headstooks for the mandrils (9, 10, 11) are the headstooks for the mandrils (9, 10, 11) are largely a supports of the whole in the given in an appear of the new portion presented at each turn, of course the whole circumference would eventually be cavered. At D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the strew d. D there is a cogged wheel fixed on the str from time to time, and the cutter made to operate on

place of F, and the wheel G stay he charged in like meaner. This lest wheel is fixed to the tame axis as the draw E, having its beneing in a sociat cast on the core frame: a third this, diens is called the castne core frame: a third this, diens is called the castne core frame: a third this, diens is called the castne core in a wife could the cast of which are lated to the footing-table in each of the band of an existing to a cast-ipon plate which is used between the centres for fixing busts, resulted, and other characters tubicets which require a which is used between the centres for fixing busts, resulted, and other characters tubicets which require a winds of the band of the centre of P on the major by this to resert all the parts O P O is the here, and other elaborate subjects which require a style of motions in order that the cutter and tracer to state to zero. All the parts OPQ is the of the plate; S is the centre, which works on the tracer to the plate; as shown at S i, in the nde elevation of the centre is the centre in the other end of plate, to work on that of the back headstock, B is passe, to work on that of the back headstock, it is an or carrier, which fits into a bole in the face-age of the front headstock, T U is the chuck for the table in the plate, it is furnished with a spill turning in structs in the plate, with cogs in its circumference, that the detent V may fix it in any required pos-tions. When the work and pattern are mounted in this when the work and pattern are mounted in this way, the workman can move it to say angle about the axis BW, and also to any angle about the axes X, Y, and, somequently can bring the cutters perpendicular for every side of it except that by which it is fixed to the search. Of course a number of these turningto every dide of it except the starting places may be used at one time, as already explained in other cases; and when the checks are moved, each must be moved through the same angle. The mode of using this machine is as follows — Let us suppose that an original carring has been produced by hand, of which a number of copies are required. If the same subject is to be often repeated, it will be found expedient to get a metal cast of the original carring for the pattern. This is fixed to the floating-table of the machine under the trace, as shown at define. expedient to get a metal cast of the original carring for the pattern. This is fixed to the floating-table of this machine under the trace, as shown at d e f s. figs. 1 and 3. On each side are fixed pieces of wood or other maternal of the proper size to carve the subject out of, as at h i j k, and the number of these patterns which can be executed simultaneously is only limited by the relative size of the work and of the machine. In the drawings two only are shown. Having fixed the tracer in its socket, and adjusted the enuters (m, m) so that they are over the centre lanes of the blank pieces,—when the tracer is over the section like of the pattern,—and brought the points of these to the same level, the machine is ready to be set in motion. When the cutters are at full speed, they must be brought into action by withdrawing the matters of the foot from the treadle, and thus allow the autters to come down, which will immediately out the authors to come down, which will immediately cut away some superfluous part of the material, and then by gradually moving the table about by hand, and, keeping the tracer constantly floating over the wife the tracer constantly floating over the is diamediately produced on as many pieces as may have been put down for the purpose Some of the leading forms of the cutters are shown at figs 6, 7, 8, 8, 10, Fiste XXVII The outline of the figures is the forms of the tracer, and the dotted lines show that of commerce, the kernels of which are desicious. An irrad of the tracer, and the dotted lines show that of the ecoresponding cutters. Spirals of any pitch may be obtained by using the change wheele F, G, fig. 4, Plate LAYALL, are gear with the hand K, the cross motion of the table from right to left being stopped by dropling the detent Y into the cogs of the wheel X as be table from right to left being stopped by dropling the detent Y into the cogs of the wheel X as the table from right to left being stopped by dropling the detent Y into the cogs of the wheel X as the table from right to left being stopped by dropling the detent Y into the cogs of the wheel X as the table from right to left being stopped by dropling the detent Y into the cogs of the wheel X as the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to the cogs of the wheel X as the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the table from right to left being stopped by dropling the required section of the groom state, with stems swollen at the joinings, and opposite the part of the principal state of the subject of the table from right to the cops of the wild specific to the subject to the subject to the table from the subject to the s where at the extress point is a dotten lines show that of the corresponding cutters Spirals of any pitch may be extended by using the change wheels F, G, fig. 4, Plate EXYEM, in gear with the hand K, the cross motion of the table from right to left being stopped by drop-ping the detent Y into the cogs of the wheel X. Some of the plants have shown flowers, as the species of Disminus, Silene, and Lychnic. From plants of the first of these genera are derived all the beautiful culti-vated varieties of the sweet-william, pink, and carna-

CANOFESTINES, keivi-o-fill-us, in Bot., a gen. of plants belonging to the nat. ord. Myrtacea. The most important epocies is C. aromaticus, the clove-tree, a native of the Moluceas, but now grown also in the lele of France, India, and the West Indias. The cloves of commerce are the unexpanded flower-buds dried. They form a well-known spice, and are much used in medicine on account of their aromatic, stimulant, and carries the aromatic. The dried purpose full aromatic. minative properties. The dried unripe fruits are called Mother cloves, and are used in China and other countries instead of the ordinary cloves, to which they are

very inferior.

CABYOSIS, kai-ri-op'-sis, in Bot., a superior one-scaled, one-scaled indehiscent fruit, with a thin, dry membranous pericarp, completely and inseparably united with the seed. The grains or fruits of the grasses, as wheat, barley, rye, and maize, are ex-

CARTOTA, kā-ro-o'-tā (Gr.), in Bot., a gen. of palms, natives of the Bast Indies. From the species-C. urcus, sugar, or jaggers, is procured, and its juice, when fermented, forms a kind of toddy or palm-wine. From the trunks of the old trees a kind of sago is obtained, and this is much used as food in Assam.

Casa, kai'-sa (Lat., a hut or cottage), was used in the Middle Ages for a convent or church: thus Bede calls Whitchurch Candida casa.

CARCADS, ka-kaid' (Fr.), denotes properly a water-fall, in which the water does not, as in the cataract, fall uninterruptedly from a great height, but in which it is broken at several parts during its sall, or it is a waterfall less than a cataract. It is generally applied to those artificial waterfalls that are met with in pleasure-

grounds and public parks.

Case, knise (Lat. casus, from cado, I fall), in Gram, is that modification which is effected on a noun to denote its relation to the rest of the sentence. commonly denoted by changes in the termination of the noun. The number of cases in the decleasion of nouns varies much in different languages. In Sanscrit there are eight cases; in Latin six; in Greek five. In English there are only three cases,—the nominative, possessive, and objective,—the last occurring only in pronouns. All the other relations of nouns are ex-pressed by prepositions.

CASE, ACTION ON THE, was a form of personal action called trespass on the case, for redress of wrongs and injuries done without force; as, for not performing a promise made by the defendant to the plaintiff, or for speaking words by which the plaintiff was defamed, or for other misdemeanour or deceit. Before the act was sed which rendered it unnecessary to describe the nature of the action in the writ, it was imperative that the declaration should be framed to comply with such description, and many nice distinctions were drawn in cases ranging between this form of action and that of trespass vi et armis (by force actual or constructive). Except to a legal autiquary, it would be practically useless to give an account of the history of this form of action, or to notice the distinctions above referred to; and this

or to notice the distinctions above referred to; and this observation will apply to the other five forms of personal actions, except that of repletin, which is one of very limited application, and different in its general character, and will be treated of in its proper place.

Cass, Pairwas's, a large flat oblong frame, generally about thirty-four inches long, fifteen inches broad, and an inch and a quarter deep. It is used by printers as a receptacle for types, and is divided into numerous compartments, each of which contains a number of treas of the same kind. A pair of cases, as controlly compartments, each of which contains a number of types of the same kind. A pair of cases, as generally used in Engiand, consists of an upper and a lower case, which are placed aslope. The upper case is divided into ninety-eight "boxes," which contain the large and small capitals, the figures and reference marks, and some other letters not frequently used. The lower case has fifty-three "boxes," which contain the smaller letters, spaces, points, &c. The behind, as a thin, clear, straw-coloured liquid. The

arrangement of the boxes in the lower use used different printing offices. The boxes in the upper are of uniform use, and the letters are placed in a betical order, as the comparatively rare use of committees the use of committees the use of the boxes depend upon the letter entained. The letters which occur most frequently in composition of the boxes depend upon the letter entained. I letters which occur most frequently in composition placed in the largest boxes, and in the most convergence of the letter of the letter of the most convergence of the letter of the product of the most convergence of the letter of the product of the most convergence of the letter of the product of the most convergence of the letter of the product of the most convergence of the letter of the product of the most convergence of the letter of the letter, the box containing it is placed in the middle of the case, and is larger than any of the case, and is larger than any of the chiefs. The type, or "letter," contained in a case is sufficient to fill three pages of this work, equal to 27,000 or 22,000 types of this small-sized letter.

CASE-HARDERING, Aurd'-en-ing (Ang.SEK), the process by which a surface or outer costing of

process by which a surface of outer resting of steel is given to iron goods, such as grates, feature, firearms, guu-locks, keys, tools, ac. It renders, any article which has been so treated for more durable than it otherwise would be, and sufficiently hard to resist the action of a common than duration than it otherwise would be, and sufficient hard to resist the action of a common file. It, makes it capable of receiving a high degree of policy when any piece of ironware is to be case-hardened is first made red-hot in a close case, surrounded a charcoal, or the burnt hoofs, akin, or benes of a sainful mixed with put and commitmed with a commitmed with a standard of the sainful mixed with but and commitmed with a sainful mixed with a large commitmed with a sainful mixed with a standard or sainful mixed with a standard or sainful mixed with a sainful mixed with a standard or sainful mixed with a sainfu charcoal, or the burnt hoofs, skin, or some of any animal, mired with salt and sometimes vinegat. It is kept in this state for a greater or less time, according to the size of the article or the thickness of the steel coating required. It is then taken out and cooled is water or oil, and afterwards polished. Sometimes yellow prussiate of potash is used, which is applied to the iron when it is red-hot; after which it is heared again, and then cooled and polished.

Clark water of Clark water when a number of

Case-shot, or Canister, kaise-shot, a number musket-balls inclosed in a metal case or cylinder, wh bursts immediately after leaving the muzzle of the gun, and the bullets radiate outwards, or scatter in all directions, like the pellets in a charge of shot fixed from a fewling piece. It is very destructive to a body of men at 250 or 300 yards' distance. Case shot are made to suit guns of different calibre. These chieffy made to suit guns of different calibre. Those chiefly used in the present day are called "Shrapnel thalls," as they were invented by an officer of the mains of Shrapnel. The case is spherical in form, like a shot or shell, and is filled with bullets and powder. It explodes by means of a fuse, which ignites when the shell is fired, and is so regulated that the case may burst just before reaching the body of men against which it is directed.

CASRINE, kai-seen (Lat. caseus, choose), is the nitro-enous principle of milk, which forms a large portion genous principle of milk, which form, appears to of the curd. Caseine, in the soluble form, appears to be preserved in solution by a small quantity of alkali contained in the milk. In the coagulated form it is readily obtained by adding dilute sulphuric acid to the milk, which precipitates in the form of a curd. The curd is well washed and dissolved in carbonate of soda, curd is well washed and dissolved in carbonate of soda, and allowed to stand for twenty-four knurs, to let the oil rise to the surface. This is skimmed off and the caseine precipitated by an acid. The process is repeated a second time, and the coggalum digeated with alcohol and ether, and dried. With all these precations the caseine still contains some saline matter, which cannot be removed. It is also obtained by coggulating the milk with hydrochloric acid. The curd is washed with dilute hydrochloric acid. The curd coagulating the milk with hydrochloric acid. The surd is washed with dilute hydrochloric acid, and finally with pure water; a guttinous mass is obtained, which is slowly dissolved by digestion at 1107, with a large quantity of water. The solution is filtered, coagulated with carbonate of ammonia, the coagulated with water, ether, and alcohol, and finally dried. Coagulated caseine is readily dissolved by the shalies and alkaline carbonates. Caseine also unites with earthy carbonates, and forms insoluble compounds. A very tenacious lute is made by mixing poor cheese with alaked lime. The most remarkable form of coagulation is that produced by the action of the secretion from the mucous membrane of the stomach. This

#### Casemate

action of rennet in this instance remains unexplained. sction of renact in this asstance remains unexpiance. Caseins has not been found anywhere but in milk. The quantity varies according to the period of lectation at which the milk is examined. Its amount also varies with different animals, as will be seen from the following table :---

Human	female		31 to	35	parts	ip	1,000.

CARREATH, kais'-mait (Fr.), in Mil., the term applied to a vaulted shell-proof chamber constructed in any work of defence, with embrasures, from which a fire can be kept up on the enemy, the artillerymen employed being protected from the enemy's shot and shell. In some fortresses, case-mated batteries are raised in tiers, one above another. Casemates were at first merely loopholed galleries, will the face of any work from which a fire of the work. built in the face of any work, from which a fire of musketry could be directed, to prevent the enemy from effecting a lodgment in the ditch in front; but in the present day they consist of vaulted chambers made of solid masonry, and as lofty as possible, every care being taken to promote ventilation and carry off the smoke, which, with the deafening reverberation of the roar of the guns, causes no little inconvenience to the officers and men employed therein. Sometimes they are made open towards the rear, or with large massive doors, that can be opened or closed at pleasure. There is generally a hole above each embrasure and a chimney in the top of the vault, which aids in carrying off the smoke when firing is going on. Casemates are also used for the reception of troops and stores during a siege, or as hospitals. For these purposes they must be at least sixteen or eighteen feet wide, and the same in height. Care should also be taken to keep them dry by covering the masonry, forming the vaulted roof with cement, and making drains to carry off the rain that may fall on the earth and turl above the roof.

CASEMENT, kais'-ment (Ital. casamento), a window which opens on hinges fixed to the side of the window-Casement windows are common in old houses, the frames which support the glazing which is set in grooved bands of lead, being made of iron. They are much used in the domestic Gothic architecture, but are more liable to admit draughts than the sash windows, and however pretty their appearance may be from without, they are inconvenient within, as the heavy wooden frames and transoms of the entire window serve to keep out the light and hide the view. The name is also given to a broad and deep circular moulding in Gothic architecture, which is sometimes enriched with rosettes placed at intervals, or folinge.

CASSOUS OXIDE. (See LEUCINE.)

OASH, Kaish, in Com., signifies ready money, bills, drafts, bonds, and all readily negotiable paper.

CASE ACCOUNT, in Book-keeping, is an account to which nothing is carried but cash on the one hand, and from which all the cash payments of the concern are drawn on the other. The balance is called the cash in hand. When the balance is in favour of the credit side, the account is said to be in cash; when in favour When the balance is in favour of the credit of the debit side, out of cush.

Of the debit and, out of cash.

Cashew Nut. (See Anagardium.)

Cashew, kash-eer' (Fr. caisser), the cash-keeper; one who is charged with the duties of paying and receiving the debts of a house of business or a society.

The cashier in many cases is called the treasurer.

Cashiers of the Bank are those officers who sign notes, and examine them when returned for payment.

and examine them when returned for payment.

Cashiebing, kish-eer-ing (Fr. caser, to break).—
When an officer of the army or nave is diamissed her
Majesty's service in consequence of scandalous and
infamous conduct, he is said to be cashiered. It is
dismissal attended with deep and indelible disgrace,
and the offender is disqualified from ever re-entering
the service from which he is thus ignominiously expelled.

Casuo, ka-se'-no (Ital., a little house, dim. of casa, a house), is a olub-house or piece for social meetings. It is derived from the Italian, and was first applied to those small pleasure retreats which noblemen in Italy usually have at some distance from their palaces, to which they occasionally retire and enjoy themselves.

Afterwards, the middle clusses united in societies, and formed similar easines or club-houses, for social enjoy-ment. The term is also applied to a building annexed ment. The term is also applied to a continuous actives to or near a theatre, where musical or dancing actives are held, and where there are also conversation and are held, and where there are also conversation and such-like. Cabilliard-rooms, refreshment-rooms, and such-like. sinos are now common in France, Germany, and other parts of the continent, and have also been introduced into England.

Casurt, kds-kct (Fr. casse), a small box or chest for holding jewels or other small articles of value. The term is also applied by scamen to a small rope fastened to little rings upon the yards; it is used in order to fasten the sail to the yard when it is to be furled.

CARQUE, kask (Fr. casque; Lat. cassis, a helmet) CASQUE, KREE (Fr. casque; Lat. cassis, a helmet), a term synonymous with helmet (see HELMET), applied to a defensive covering for the head, made of plates of steel or iron, and surmounted with a plume. It seems, from the derivation, to imply more particularly a helmet similar to those worn by the Greeks and Ronans, which covered the head only, and left the face and neck exposed. and neck exposed.

CASACTION, COURT OF (Fr. cassation, from casser, to annul, quash), is the highest judicial tribunal of France, so called from its having the power to annul the deci-sions of any of the other tribunals. It is not, strictly speaking, a court of appeal, because it does not go into the merits of the cases on which judgment has been given, but only takes up the legal bearings of the case, as to whether the due forms of procedure have been observed, and the judgment be in strict accordance with law. When a judgment is quashed, the case is remitted back to the tribunal appealed from to give a new decision. It is a court of appeal in criminal as well as in civil cases. It consists of forty-eight members, who are appointed by the sovereign, but who hold office for life. It is divided into three sections, vis.—
1. Section des Requées, which decides on the admissibility of the petitions or appeals; 2. Section de Cassaand 3. Section de Cussation criminelle, which decides upon appeals in criminal matters. The court has a president, and there are presidents also of each of the three sections; but the minister of justice, as keeper of the seals, has the right of presiding in cases where it sits on appeals from the cours imperiales. Cases of peculiar difficulty may be judged of by the three sections united; and the whole court, when presided over by the minister of justice, possesses powers not specially provided for by law; as in censuring or suspendcally provided for by law; as in censuring or suspend-ing judges, &c. This court owes its origin to the revo-lution of 1789, and it has been of great benefit to France, maintaining a unity in the legislation, and protecting the people from arbitrary proceedings or misjudgments in the other courts. In all the changes of government and administration, this court has always preserved a high character for strict impar-

CASSAVA. (See MANIHOT.)

Cassia, küsh'-e-ü (from Arab. katsa, to tear off, the bark being stripped from the tree), in Bot., a gen. of plants belonging to the nat. ord. Leguminosa, sub-ord. Casalpiniea. The leaslets of several species furnish Casulpiniea. The leaflets of several species invalue the important drug senns. Some uncertainty prevails as to the species yielding some of the commercial varies as to the species yielding some of the species and all species as a learner in senns. as to the species yielding some of the commercial varieties. That kind commonly known as Alexandrian senna is generally supposed to be derived from C. officinalis, var. lancolata, and C. oborata. This is the kind most esteemed in Britain; but it is frequently adulterated esteemed in Britain; but it is frequently adulterated with the leaves of other plants. The common Restladian, Mecca, or Rombay senna, is supposed by Royle to be the produce of C. officinalis, var. acutifolia; Timevelly seema, a very fine kind, is furnished by C. officinalis, var. clongata. The above three varieties are those generally used in this country, and are officinal in our plarmacoposiss. Other commercial varieties are, Tripoli senna, from C. achievica; Aleppo senna, from C. chorata; and American senna, from C. maritandica. Another drug, called cassis pulp, or purging cassis, is obtained from a species of this gen.; namely, C. fatials. The pulp is contained in the pods. It is of a reddish-black colour, with a sweetish teste, and possesses lazative and purgative properties. The pods of C. braziliana are used in veterinary medicine under the name of horse-cassis.

#### Cabsis-bark

The bark of C. auriculata is employed for tanning, and the flowers are said to be used for dyeing yellow. The seeds of C. Absus, under the names of Chichou and Ciamatan, are used in Egypt as a remedy in ophthalmia.

CASSIA-BARK, and CASSIA-BUDS. (See CINNAMONUM.) CASSIOPRIA, käs-se-o-pe'-s-ä, in Astron., a constellation in the northern hemisphere, midway between the constellations Auriga and Cygnus. It is not far from the north pole, and may be distinguished by five stars disposed somewhat in the form of the letter M. It contains only one star above the third magnitude, and that is not so brilliant as stars of the second. It is figured as not so formant as stars of the second. It's aggree on the celestial globe as a female figure sitting in a chair with its feet towards the pole. The name is said to be derived from Cassiopeia, the mother of Andromeda, who was made a constellation and placed in this meds, who was made a constellation and placed in this position for having boasted that she was prettier than the daughters of Nereus. Tycho Brahe observed a star of great brilliancy in this constellation in 1572, It is said to have appeared there in 945 and 1264, but this is doubtful; yet if this were the case, Sir John Herschel considers that it may reappear in 1872.

reappear in 1872.

Cassock, khá-sok (Fr. casaque), a kind of surtout or long upper garment, now usually worn only by the clergy, but formerly by all classes. As worn by the English clergy it is black, with a single upright collar; but on certain state occasions bishops sometimes wear purple cassocks. In the Church of Rome they vary in colour with the dignity of the wearer; those of the priests being black, bishops purple, cardinals scarlet, and ponce white.

and popes white.

Cassowary, kisi-so-wā-re (Casuarius), a gen. of large and powerful birds closely allied to the Ostrich. It is an inhabitant of Java and the adjacent Indian archipelago, and is generally called the helmeted cassowary, on account of an osseous crest or horny helmat which surmonnts its head. The skin of the head and the upper part of the neck are without feathers, and of an intense blue and deep red colour. There are also two pendent wattles, partly red and partly blue, on the front of the neck. On the breast is a bare place, on which the bird rests when lying on the ground. In height it is less than the ostrich, standing little more than five and popes white.

CASSOWARY.

feet when erect. It is, however, robustly built, and reet when erect. It is, however, roomsty built, and sery strong. From the appearance of its eyes and the form of its head, the cassowary might be supposed to be of a fierce and threatening nature. This is not the case, as it is rather timorous and shy than otherwise. When attacked, it defends itself by kicking backwards with its feet, and striking with its short and otherwise useless wings. All the feathers of the cassowary are of the same kind, and of the same colour: they are only designed for covering. Its whole plumage is very poorly supplied with feathers, and, at a short distance, it presents the appearance of a rough coat of coarse

#### Casto

cept the ostrich, is becoming very rare in its native regions; but there are specimens to be seen in most of

regions; but there are specimens to be seen in most of the menageries of Europe.

Cassythaches, kis'-se-thai'-se-e, in Bot., the Dodder-Laurel family, a small nat, ord, of plants separated from the Lauracea by Lindley. There is only one gen.—Cassytha, which includes nine species, natives of tropical regions, and distinguished from the species of Lauracea by their parasitical habit, by their scaly modified leaves, and by the fruit being inclosed in a succulent calys. Their uses are unknown.

Casse kint (Den Lauracea).—The tearn cast is generally.

Succulent calyx. Their uses are unknown.

Caer, kāt (Dan. katter).—The term cast is gagerally employed to denote a statue, bust, or the resemblance of anything that may be formed by pouring plaster of Paris in a liquid state into a suitable mould. It is also applied to articles of cast-iron and other metals. Impressions or casts are taken from the human-face by inserting paper funnels into the nostrils, and then pouring liquid plaster of Paris over the face, which has been previously greased, to prevent the adherence of the material employed. It rapidly hardens and becomes fit for removal. The cast thus taken forms a mould from which casts of the face may be procured. The process is useful in multiplying copies of works of art executed in marble, architectural details, &c. In angling, the line with the coller and flies attached is called a cast; and we commonly use the expressions called a cast; and we commonly use the expressions "cast in the eye," "cast of countenance," and " oast of hawks," in hawking, when a number are let loose at once.

Once.

CASTANEA, kūš-tai'-ne-d, in Rot., a gen. of plants belonging to the nat. ord. Corplacea. The species are familiarly known as chestnut-trees. C. vulgaris or vesca is the Spanish chestnut, which is much outlivated for timber, and for its edible nuts, which form a principal part of the food of the poor in the south of Europe. C. americana, a native of the Northern States of America. Dodines a much smaller. but very sweet of America, produces a much smaller, but very sweet nut. The chestnuts eaten in Britain are chiefly imported from Spain.

CASTANETS (Sp. castaneta, or castaneta, probably from castaña, a chestnut), a small musical instrument of percussion, much used by the Spaniards and Moors in their dances. It consists of two small round pieces of hard dried wood, or of ivory, hollowed out in the centre, and placed together, with the concavities inwards, and fastened to the thumbs. The fingers being rapidly struck assened to the numbs. In a migra coing raphy serious upon them, a tramulous sound is produced, which marks the measure of the dance. The use of this instrument was probably brought by the Moors from the East into Spain. It is now frequently used in ballets and operas. The cretaion of the ancients was a similar instrument.

CASTE, kast (Port. casta, a breed), in general, is applied to the several classes or orders into which communities are sometimes divided, with hereditary burdens or privileges; more particularly it is applied to that division into classes which prevails in India. The Portuguese, who were the first of European na-tions to establish themselves in India, found there a very strict distinction maintained between the different classes of society, to which they applied the term casts. Hence the term has also come to be applied to such social distinctions among other nations as are made to depend upon birth or fortune. The distinction of castes has existed in society from the very earliest times. In Egypt, Assyria, ancient Persia, and over almost the whole of Asia, it rises beyond the period of history. In Egypt the division into castes existed as early as the time of the Phasacha the principal of as early as the time of the Pharaohs, the principal of as early as the time of the Pharaols, the principal of these being the priests, soldiers, husbandmen, watermen, and herdsmen. In Persia, even before the time of Zoroaster, the people were divided into four castes; viz., priests or magi, soldiers, husbandmen, and tradesmen. It is highly probable that these divisions were originally founded upon differences of descent, and originally lounded upon differences of descent, said that the separate cases were at first separate races of people. Among the Hindoos society is divided into four castes:—1. The Brahmins, or priests; 2. the Cohatrys, or military class; 3. the Vaisys, or mercantile; and 4 the Sudra, or service class. The Brahmins or exported to have precaded originally directly with the property of the property as presents the appearance of a rouga coas of coarse cantile; and 4 the Sudra, or service class. The break hair. It feeds upon eggs, fruit, and succulent herbage.

The eggs of the cassowary are greenish in colour, and have a much thinner shell than those of the ostrich.

This peculiar bird, which is the largest known exflicing, and assisting others to sacrifice. The most

exalted of men, even kings themselves, are infinitely inferior to the meanest of Brahmins. The least disrespect shown to one of the secred order is the most atractions of armes. Neither the body nor property of a Brahmin can be touched, even though guilty of the worst of crimes. "What men desirous of life would be to the control of the worst of crimes." injure those by the aid of whom worlds and gods perpetually subsist?" The Cahatryas, or military caste, sprang from the arm of Brahms, and, though looked down upon by the Brahmins, they are looked up to by the other castes with a veneration only inferior to that paid to the Brahmins. It is said that the saver-dotal order cannot do without the military, nor the military without the sacerdotal, the prosperity of the one depending upon the other. It is the duty of the Oslattra to defend the people, to give alms, to sear-files, to read the Veda, and to shun the allurements of sensual gratification. The Vaisya, the agricultural or sensual grantication. The Vanya, the agricultural or newcantile class, sprang from the thigh of Brahma, and their duty is to keep cattle, to cultivate land, earry on trade, lend money at interest, sacrifice, bestow gifts, and read the Veda. The Sudra, or service class, proceeded from the foot of Brahma; and a chief part of their duty is to serve the other castes. The most abject and grovelling submission is imposed upon them as a religious duty, and enforced by the most cruel punishments. No Sudra must amass wealth, and a Brahmin may seize, without hesitation, the property of his slave. Neither are they allowed to read any of of his slave. Nother are they allowed to read any of the sacred books, nor to be instructed in the principles of religion. Besides these four castes, there exist in India a large class of persons called Pariahs or Chandalas, who are regarded as the outcasts of society, objects of contempt and diaguat, with whom no one of caste can hold any intercourse. The loss of caste is one of the most serious calamities that can befall a Hindoo. This, however, results not from immoralities, for the most abandoned Brahmin retains his rank, notwithstanding his crimes; but he will entirely forfeit it, and lose all countenance in society, by touching inpure food, or some such petty delinquency. Mix-ture of castes, though not absolutely forbidden, involves disadvantages upon the offspring. The different castes have become so much intermixed, that the pure races can scarcely be said to exist in the present day, except among the Brahmins; and, from the state of society, distinct employments can now no longer be maintained. A Brahmin who cannot find employment in his own line may descend to the exercise of military duties, or tillage, or traffic. A Cshatrya and a Vaisya may also have recourse to inferior employments without loss of caste. The Indian armies are now not confined to one, but are recruited from all castes of the commu-From the intermixture of the races, innumenity. From the intermixture of the races, innume-rable mixed tribes have sprung up, who form castes among themselves.

CASTELLAN, kas-tel'-lan (Lat. castellanus), the go vernor of a castle or the constable of a fortified house. It was also the name of a dignity or office in Poland, the castellans constituting a kind of lieute-nauts of provinces, and commanding a part of a pala-tinate under the palatine. They also formed a lower class of senators of the kingdom, and sat on low seats

ciass of semators of the kingdom, and sat on low seats behind the palatines or great senators.

\*\*Castrination, kis-tel-lai'-shun (Lat. castellatio), in the Middle Ages, denoted the building of a castle, or the fortifying of a house to render it a castle, which, by the ancient laws of England, required the king's attacks. antherity.

CASTIGATION, kus-te-gai'-shun (Lat. castigatio), denotes punishment, correction, or discipline. Among ment inflicted on offenders by beating with a wand or

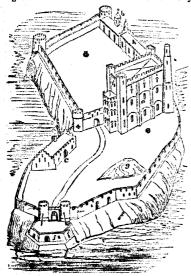

Casting, kast'-ing, a term applied to the process Observed, kest-ing, a term applied to the process of pouring a metal or some other substance, in a fluid or semi-fluid state, into a mould, which is made in various ways, and of substances best suited for the material which is to be poured into it. The fluidity of material which is to be poured into it. The limitity of the substance may be produced by heat, or some other agent; but the cast always solidites in the mould. The process is applied to the manufacture of articles in fron, bronze, bell-metal, lead, steel, copper, porce-lain, plaster, and cement of various kinds. The method of casting cannons in iron and bronze will be found

elsewhere. (See CANNON.) The process adopted in casting statues in plaster, and making ornamental pot-tery and busts in Parian ware, differs materially from that which is used in forming metal castings. process will be found described in the notice of that branch of art to which it respectively belongs. (See PORCELAIN, POTTERY, SCULPTURE.) The process of forming or founding iron castings of great size, and bells and statues in bell-metal and bronze, will be found

described under the head of FOUNDING.

CASTING VOTE, is the vote which is given by the president or chairman of a meeting when the votes on each side are exactly equal; and thus the point at issue is decided by the casting vote. Sometimes the chairman has a casting vote in addition to his vote as an ordinary member; at other times, he has only a casting vote. The speaker of the House of Commons has only a casting vote, and whon, as has sometimes happened, it is necessary to give it, it is generally on that side which will admit of the question being reconsidered.

CASTLE, kus'-l (Lat. castellum, a fort or small camp), the name former), given to a strongly-fortified build-ing inclosed by walls, and intended for a place of residence, calculated to afford protection against the attack of an enemy. The buildings to which this term is applied were chiefly the residences of the nobles during the Middle Ages, and were erected in the reigns of the Norman and Plantagenet kings while the feudal system existed in this country. Castles are said to have been built in many parts of England by the Saxons and Danes, but they were not of the strength and size of the Norman castles. The Romans erected many strongly-fortified camps in various parts of the country, called castella, which were garrisoned by small bodies of troops. These were afterwards used as works of defence by the Saxons, and turned into castles by the Normans by the addition of the massive keep and berbacan, with towers here and there at the angles of the outworks; but with the introduction of the feudal system by William the Conqueror, that monarch and his followers, among whom the country was parcelled out, commenced the building of the castles whose picturesque remains give additional interest to many a beautiful bit of English scenery, and are intimately associated with historical events and legendary lore. The erection of these baronial fortresses was effectively continued in the succeeding reigns, no less than 1,115 having been built in the troublous times that marked the reign of Stephen. The great strength of the castle, and its capability of resistance to the imperfect artillery of the day, consisting of the trebuchet, balista, man-gonel, and other machines, from which stones, darts, and fireballs were hurled at and within the walls, rendered the barons insolent and oppressive, as they could not only defy the forces which a neighbouring baron might lead against them, but even those of the king himself. The unfortunate Saxons and people who were held in thraidom, passing with the land itself from one master to another, were obliged to labour at the will of the baron who owned the district, in the erection of these strongholds, which afterwards be-came the scene of many a deed of violence and wrong; and, indeed, the insolence and lawless conduct of the barons attained such a height, that, in the reign of Henry II., no one was permitted to erect a castle without the permission of the crown; and this was seldom granted without sufficient cause, for the castles had become the retreats of rufflans who menaced the life and property of all around them whenever an op-portunity offered itself. The baronial castle, however, often formed a nucleus for a town, and many a pros-perous and thriving English town and city can trace its rise from the few mean dwellings that a noble's re-tainers erected around and close to the castle of their tainers erected around and close to the castle of their feudal superior for the purpose of mutual security and defence. The principal parts of the Norman castle were the keep or donjon, the courtyard or bailey, as it was sometimes called (see Balley), the walls that surrounded the court, the barbacan or gatehouse (see Barbacan), and the ditch or most. Sometimes an inner court was made within the outer one, immediately cound the learn age, surrounded with walls which round the keep, also surrounded with walls, which served as a second line of defence when the enemy had taken the barbacan and occupied the outer court. Outbuildings were also added to serve as a chapel, stables, and lodgings for soldiers, with a mound between the barbacan and keep, from which it is supposed that the baron dispensed justice to his retainers. The keep was usually a square tower of enormous strength; the walls were from twelve to twenty feet in thickness at the base and about eighter ten feet wide at the top: they were surmounted by battlements. A narrow winding staircase, generally in one of the angles or a projecting turrer, gave access to the first floor, where the entrance to the interior of the castle was situated. The chambers were small, and insufficiently lighted by narrow windows set in smail, and insumerously igneed by narrow windows set in deep embrasures. The walls also contained small chambers and galleries here and there, and staircasses giving access to the battlements. These passages were loop-holed, to admit the light, and for purposes of espial and defence. The keep was generally buttressed, and had defence. circular towers or bastions at the angles, one of which circular towers or deathous at the angies, one of which rose above the rest, to afford a lookout-post for the warder or sentinel on guard. A good example of the old Norman keep will be found in Norwich Castle, and those of Rochester, Conisborough, and Newcastle. Sometimes the keep was built in an angle of the outer sometimes entirely within it; and it was often erected on an artificial mound, like the Dane John at Canterbury, which probably derives its name from having been at some time or other surmounted by a

CASTLE.

keen or donjon. It was divided into four stories, of which the basement was set apart for stores, &c.; and below the basement was generally a dungeon for prisoners. The first floor served the purpose of a common hall, with small withdrawing-rooms or private chambers attached. The second and third floors were divided into apartments for the owner of the castle and his family, and sleeping-chambers for his guests and domestics. The arrangement of castles that were built at a later period, such as Windsor Castle, Kenilworth, and others, was more complicated, and the buildings covered a greater area. Jousts and martial exercises were carried on in the court-yard, the walls of which were strengthened with towers and bastions, furnished with battlements, loopholes, and machicolations. The barbacan formed a fortified entrance to the court-yard, with a portcullis and necessary defences. From this the drawbridge, which afforded the means of passage over the surrounding most, was raised and lowered. The Scottish fortalices and psel-houses, particularly those on the border, were not of the size and strength of the English castles. They consisted chiefly of a square tower with battlements and bartizana (see

BARTIERN): it was surrounded by a most whenever at was possible to do so, and every advantage was tall of its natural position to secure it from attack or s of its latural position to secure it from attack or sur-prise. In the accompanying illustration denicting a Norman castle, and copied from Grose's "Military Antiquities," there are shown:—b, the shapel; t, this stable; d, the inner bailey; s, the outer bailey; f, the barbacan; g, the mount; h, the lodgings of the soldiers. —Ref. English Cyclopedia—Arts and Sciences; Brit-ton's Architectural Antiquities; Bayley's Ancient Custles of England and Males. of England and Wales.

CASTOR, the Beaver. (See BI CASTOR OIL. (See RICINUS.) (Sec BEAVER.)

CASUARINACER, kas-u-ar-in-ai'-se-e, in Bot, the Beefwood fam., a nat. ord. of dicotyledonous plants in the sub-class Monochlamydea. There is but one genus, Casuarina, which includes about thirty-two specie principally natives of Australia. They are very peouliar trees, with slender, wiry, drooping, jointed branches, which have no evident leaves. The name Beefwood was suggested by the colour of the timber resembling that of raw beef. The wood is also known under the names of Botany-bay Oak, Forest Oak, He Oak, and She Oak. It is imported in considerable quantities, and is used in this country for inlaying and marqueterie.

CASUISTRY, kus'-u-ie-tre (Ital. Span. casuista; Fr. casuiste; from Lat. casus, a case), is that branch of ethical science which professes to deal with cases of conscience. It lays down rules or canons directing us how to act in all matters of moral doubt; whether and how far an obligation is binding upon us, or may be relaxed or dissolved, on account of concomitant eix-cumstances. Its rules are drawn from revelation, reason, the canon law, authority of the fathers, &c. This science has been chiefly cultivated by the Roman Catholics, and was much studied in the 15th and 16th Catholics, and was much studied in the 15th and 18th centuries, especially by the Jesuits, being admirably calculated to advance the policy of that order. The confessor, who was able to lay down exact rules of conduct, and to decide which was the greater of two sins, obtained agreat power over his penitent. Indeed, the science has been said to have had its origin "in the distinction between mortal and venial sin," and has not insufficed by the art of quibbling with the distinction between mortal and venial sin," and has not inaptly been termed "the art of quibbling with God." This science, however, has been cultivated in the Protestant as well as the Roman Catholic church, and there was, until recently, a professor of casuistry in the Cambridge university.—Ref. Mayer's Bibliothees of Cassists, where they are arranged under the three heads of Lutheran, Calvinist, and Roman.

Casus Brill, kai'-sus bel'-li (Lat., the cause of war), is the reason assigned by one nation for moint to war

is the reason assigned by one nation for going to war

with another.

CAT, kat (Felis).-It is not a little singular that the origin of the most important member of this family, the domestic cat (Felis domesticus), should be involved in such obscurity. By the older naturalists it was in such obscurity. By the older naturalists it was supposed that it might be considered to be descended from the wild cat (Felis catus-ferus). Modern science from the wild cat (Felis catus-Ferus). Modern science has upset this theory by bringing a tremendous array of argument, and battering at its most vulnerable parts. In its place another theory has been substituted, and accepted generally by naturalists. It is well known that the ancient Egyptians possessed a domestic animal, which, judging from representations of it on the monuments of Thebes and elsewhere, bore recombined to the control of the control emblance to our domestic out. Moreover, in the a resemplance to our domestic oat. Moreover, in the British Museum there is a copy of an Egyptian painting, which is supposed to represent the cat of that country catching birds; and it is conjectured that it was trained for that purpose. This same animal has been referred to as being not unlikely the progenitor of the domestic cat; and the probability of this theory and the probability of this theory are proposed. or the domestic cat; and the probability of this theory has been augmented by the discovery of a species (Felis maniculata) by Rüppel in Nubia. This animal is said to be about the size of the domestic cat, and one-third smaller than the wild cat. Rüppel gave his opinion that it must be a descendant of the domestic cat. opinion that it must be a descendant of the domestic cat of the Egyptians, and that, at some remote period, it was transferred to the Europeans by the contempo-rary Egyptians. This opinion has been adopted by many eminent zoologists, amongst whom may be man-tioned Temminck, and fir William Jardine in our own country; the latter, in particular, has some very inge-

Catacom be

nions remarks thereupon, which may help considerably to elucidate the difficulty connected with the origin of Felis domesticus. There does, indeed, seemmuch in favour reassomesticus. There does, indeed, seemmuch in favour of Rüppel's theory; only, so the other hand, we have naturalists of equally heavy calibre dissenting from it. An authority whose opinion cannot be too highly estimated in all that relates to natural history thus alludes to Felis musiculata — "This species, to which the big authority of Rüppel has assigned the origin of our house-cat, is still further removed from it in essential colorised absenters then some the Rivitis wild at the zoological character than even the British wild cat, to which it has been previously so generally referred; and that, as in the case of so many of our domesticated animals, we have yet to seek for the true original of this useful, gentle, and elegant animal."—(Bell, History of British Quadrupeds.) Dallas also makes a similar statement in his "Animal Kingdom." Mr. Bell not only denies the correctness of Ruppel's theory, but deals a death-blow to Sir William Jardine's and other naturalists' notion of the crossing of the wild and tame cat. "It is not without much reflection on the matter," says he, "that I have come to the con-clusion that this opinion of their intermixture, repeated and transmitted from one to another till it has become an uncontested dogma, is erroneous, and has its foun-dation in mistaken facts." This emphatic declaration from so eminent a zoologist is a little startling; but, with all deference, we must still incline to the opinion that the intermixture of the two breeds is far from improthe mermixing of the two breeds is lat from impro-bable. It would seem that the subject of the origin of domesticated animals is fraught with considerable difficulty. It has engaged the attention of numerous zoological societies for some years, and but little pro-gress has been made. The wild cat is found in all the wooded districts of Europe,—in Germany, Russia, and Hungary: it is also found in the north of Asia and Mepaul. In Great Britain it was at one time abundant, and met with in all the woods and forests. From a charter granted to the abbot of Peterborough, in the reign of Richard II., we learn that the wild cat was one of the animals hunted in those days. Its hide was probably not very highly valued; Archbishop Corbyl's canons (1127) ordained that the nuns and abbesses should not wear a more expensive apparel than that made of wild cats or lambs' skins. At the present time, the number of wild cats inhabiting England is not very large, and they are principally found in the northern counties. In Ireland, and more particularly in the north of Scotland, they are still found in large numbers. Pennant's description of the wild cat is very smusing, although perhaps more applicable to the animal of his time than our own. "The wild cat," says he, "may be called the British tiger; it is the flercest and most destructive beast we have, making dreadful havoe among our poultry, lambs, and kids. It inhabits the most mountainous and woody parts of these islands, living mostly in trees, and feeding only by night. It multiplies as fast as our common cats; and often the femsles of the latter will quit their do-mestic mates to seek the forest home of the wild spemesse mates to seek the torest nome of the win spe-cies." The domestic cat is so well known that any description of it would be unnecessary. In the town and the country, in the mansion of the rich and the cottage of the poor, in the workshop of the artisan and the offices of the merchant, this well-known animal may be commonly found. It is of many colours and sizes: there is the black cat, the tabby, the tortoiseshell, the white, the slate-coloured, the blue or Chartrense, the dun-coloured cat, and a few others, the most beautiful the slate coloured. tiful of which, perhaps, is that known as the Angora cat, with its long silky hair. As a domestic animal it is greatly prized, and its services are extremely valuable; but as a companion of man it does not rank very highly. It displays very little of that affection, nsy, absolute devotedness, so characteristic of the dog. It is more attached to locality than to its owner; and there are numerous instances on record of its deserting a family in whose service it has been living for years, on their removal from a residence in which it has been on their removal from a residence in which it has been brought up, and to which it will return, even though it be under the rule of strangers. Perhaps one of the most admirable qualities of the cat is its extreme devotion to its young; for their sake it will brave the greatest danger, and its uneasiness at finding them removed, only for a few minutes, is familiar to all. The

numerous anecdotes of its maternal care alone would fill a volume. The extraordinary artifices it will resort to to secure its young are astounding, and seem simost human in their character. The period of gestation is sixty-three days, the young remaining blind nine days after birth.

CAT, in Mar., is a term used in various ways, according to the words with which it is joined. Its principal significations are the following:—Cat-fall, a rope used to heave up the anchor from the water's edge to the bow. Cat-harpings, small ropes for bracing the shroads to the lower masts behind their respective yards. Cathads, two strong short beams of timber projecting over a ship's bows on each side of her bowsprit. Catblock, a two or three-fold block, used to draw the nuchor up to the cat-head by means of an iron hook, called the Cat-hook, which is fastened round it. Cat-o-wine-tails, an instrument composed of nine thongs of line or rope, about half a yard in length, having on each three knots tied at regular distances; to this a

piece of very thick rope is joined as a handle.

CATABAPTISTS, kūt-ā-bāp'-tiste (Gr. kuta, sgainst, and baptiso, I baptize), is applied to presons opposed to baptism, regarding it either as a rite altogether obsolete, or as applicable only to converts from another addition.

religion to Christianity.

CATACHRESIS, kùt-ü-kre'-sis (Gr., abuse, from kata, against, and chroomai, I use), is applied to a figure in rhetoric in which an improper in place of a proper term is used. It occurs when, for want of a proper word to express a thought, one is added which comes near to it; as when it is said of the Greeks,—

## "They build a horse by Pallas' art divine."

It is frequently used by poets for novelty, or to give additional force to the expression, when the proper word is not strong enough; as when Milton, in describing the descent of Raphael from heaven, says that he—

# "Sails between worlds and worlds."

CATACOMBS, katt-u-komes (Gr. kata, in the sense of "below," and kumbos, a hole or hollow), vaults below the surface of the earth, used as burial-places for the dead. There are many of these subterranean excava-tions, in the form of long galleries and chambers, in many parts of Europe. They are to be found at Syracuse and Palermo, in Sicily, and in Asia Minor, Syria, Egypt, Persia, and Greece: some have also been discovered in South America. The catacombs of Rome. Naples, and Paris are the most famous ; they are cut out of a soft calcareous rock that is easily quarried. The catacombs of Rome are on the Via Appia, or Appian Way, not far from the city; they are said to extend for twenty miles underground; but they cannot now be explored for more than one-fourth of that distance, and many parts have fallen in, which causes a visit to them to be attended with some danger. It would also be hazardous in the extreme to visit the catacombs without a guide, or to become separated from the party with whom one may be traversing these gloomy vaults and galleries, which wind about in all directions, and cross each other like the turnings of a labyrinth. The passages are about eight feet in height and five in width; the graves are hollowed out of the sides, forming three tiers one above another. When the body had been deposited in the cavity assigned to it, it was walled up, and an inscription, generally con-fined to D. M. (Deo Maximo), with a few brief particulars with reference to the name, age, and calling of the occupant of the cell, was cut on the stones that formed the closure of the tomb. At intervals there are large vaulted chambers, which form a centre in which many of the passages meet, and which appear to have been used as places of worship. They are furnished with altars, and are ornamented with fresco-paintings, inscriptions, sculptured crosses, and crucifixes. Some of these chambers, or chapels, are said to have been formed by order of some of the popes of Rome. The carly Christians used the catacombs as places of wor-ship and cemeteries for their dead; but it is most pro-bable that they were excavated and used for this purpose prior to the Christian ers. The catacombs at Naples are similar in construction to those at Rome, and were used by the early Christians for the same purposes. They are adorned with fresco-paintings of

#### Catafaloue

great freshness of appearance, among which the palm-tree is conspicuous as an emblem of Palestine. The galleries of the Nespolitan catacombs are wider than those of the catacombs at Rome. Those at Palermo and Syracuse are characterized by greater regularity of construction, and are filled with the tombs of heathens and Saracens as well as of Christians. The catacombs of Egypt are inferior to those of Italy in size; many of them were explored by Belzoni, who brought from thence the sarcophagus of Psammetichus the Powerful, who flourished about 650 s.c., made of alabaster, and most beautifully sculptured. Catacombs of considerable extent were discovered about a hundred years since in the hill of Tarchino, about three miles from Corneto, in Italy, the site of Tarquini, one of the twelve republics or representative cities of the ancient Rituria. They are remarkable for the beauty of the decorations, paintings, friezes, mosaics, vases, arms, and other archieological remains that have been dis-They are remarkable for the beauty of the covered in them. The catacombs of Paris extend under the city for a considerable distance; they were formerly quarries, from which the stone that was used in build ing the old city was excavated. They have acquired the name from having been made the receptacles of skulls and bones removed from the churchyards and cemeteries within the confines of the city, which had become inconveniently crowded with human remains The passages present a singular appearance, the bones having been arranged in the form of crosses and other patterns over the surface of the side-walls. The remains of many of those who were so ruthlessly slaughtered in the revolution of 1792 were thrown into the cata-combs.—Ref. D'Agincourt's History of Art by its Monuments, vol. i.

CATARLAGE, kāt'-ā-fālk (Ital. catafalco, a scaliold), an elevated tomb, usually a temporary structure of carpentry, decorated with painting or sculpture, and containing the collin of a distinguished person, round which tapers, ornamouts, inscriptions, armorial bearings, &c., are disposed. It is generally placed in the middle of a church or large hall. The surcophagus is exposed for show upon an elevation covered with black cloth, and is laid beneath a canopy and surrounded by caudelabra. Some mark or insignia of the rank of the deceased, as a baton, an epsulette, or sword, is placed upon the coffin. In the case of a sovereign or member of a royal family, princely or ducal trophics are

nade use of.

CATALBOTIC, kāt-ā-lek'-tik (Gr. katalektikos, deficient), is a term used in Greek and Latin poetry to denote a verse wanting one syllable of its proper length. Acatalectic is applied to such as are complete, and hypercatalectic to such as have a syllable too

many.

CATALEPSY, kit-ü-lep'-se (Gr. katalepsis, from kata, down or into, and lambano, I seize), in Path, is a disease characterized by a sudden deprivation of sensation and voluntary motion. The attack usually comes on without any warning, and during the paroxysm the patient remains in precisely the same position as he was in at the moment of attack. The circulation and respiration are in most cases but little affected; but cocfisionally they are greatly depressed, and are sometimes even imperceptible. The attack may last only for a few minutes, or it may continue for hours, and even, it is said, for days; and consciousness generally returns with the same suddenness as it left, the patient having no recollection of anything that passod during the attack. This disease bears a great resemblance to thor measurements attack. This disease bears a great resemblance to the measurement of the measurement of the first of the first of the measurement of the measurement of the first of the first

stomach; and strong ammonia applied to the nos-

trils.

Carlogus, kdt'-à-log (Gr. katalogos, from katalogos,
I register), denotes generally a list or register of things
one by one,—an enumeration of particulars. More
strictly and commonly, it is applied to a list or register
of books in a library. A catalogue of some sort is
absolutely necessary in every large library; but the
plan on which it may best be constructed is a subject
that has given rise to much discussion, and on which
much difference of opinion exists. Each of the proposed plans has its advantages: and there are nowposed plans has its advantages; and there are non-without their disadvantages. They may all be divided into two great classes,—the alphabetical and the classi-fied; in the former the books being arranged alpha-betically, according to their authors or titles; in the latter classified in some way or other according to their subjects. The alphabetical arrangement possesses the advantage of being much more simple, and more easy of consultation; but then people frequently require to consult catalogues for books on particular subjects, of which they know neither the author nor title. To meet this difficulty various attempts at classsification have been made, but all have more or less failed. They have generally been founded upon some attempted classification of human knowledge, in secordance with some theory, either of the powers or functions of the mind itself, or of the order and succession in which the phenomena of the material world may be conceived to present themselves to its contemplation; but, from the time of Bacon downwards, all attempts that have been made at discovering a natural system of classifying all knowledge have been marked by failure. For an account of the multitudinous schemes that have For an account of the intintulations schemes was asset been devised for the cataloguing of books on any such plan, we can only refer for further information to such works as J. F. M. Albert's "Recherches surles Principes works as J. F. M. Albert's "Recherches suries Frincipes fondamentaux de la Classification bibliographique," Paris, 1847; T. H. Horno's "Outlines for the Classifi-cation of a Library," 1825; F. A. Ebert's "Bildung des Bibliothekars," 1820; Brunet's "Manuel du Libraire" (Introduction). Generally, the catalogue-makers now, in place of attempting to solve some of the knoticest problems that have ever puzzled the brains of metaphysicians, content themselves with adopting some convenient and easily-understood classification of the convenient and easily-understood classification of the various branches of literature. It may interest our readers that we give here the heads of a scheme proposed by Mr. E. Edwards, a geutleman of great experience in this way, and one well entitled to speak with authority on the subject. He gives it as particularly suited for a town library (Memoirs of Libraries, vol. it. p. 815, et seq.) Class I. Theology.—I. Holy Scriptures; 2. Sacred philology; 3. Collective works of theologians; 4. Dogmatic and polemic theology; 5. Catechetical theology; 6. Pastoral and hortatory theology. chetical theology; 6. Pastoral and hortatory theology; 7. Mystical theology; 8. Liturgies and treatises on ecclesiastical rites and ceremonies; 9. Works relating to Judaism; 10. Natural theology. II. Philosophy.—1. Collective works of philosophers, and general treatises on philosophy; 2. Treatises on ethics, or moral philosophy in particular; 3. Treatises on metaphysics, or intellectual philosophy in particular. III. History. or intellectual philosophy in particular. III. History,
—1. Works on the composition and study of history,
and on its objects and uses; 2. Universal history and
biography; 3. Ancient history and biography; 4. History of the Middle Ages; 5. General ecclesiastical history; 6. History of Modern Europe generally; 7.
History of Great Britain and Ireland; 8. Modern history of the other countries of Europe; 9. History of
Apparies, 10. Modern history of Africa and of Asia. America; 10. Modern history of Africa and of Asia. America; 10. Modern instory of Arious and of Asia.

IV. Politice and Commerce.—1. General treatises on politics; 2. National constitutions and treatises relating thereto; 3. Treatises on monarchy; 4. on parliamentary representative assemblies; 5. on the administration of civil government; 6. General treatises on law; 7. Collections of laws, and expository treatises on law; 7. Collections of laws, and expository treatises thereon; 8. Treatises on the criminal laws; 9. Political economy; 10. Treatises on church establishments, religious liberty, and matters connected therewith; 11. on public education; 12. on armies and navies—their organization, maintenance, and discipline; 13. on foreign policy, and on the rights, duties, and payment of ambassadors and consuls; 14. Political satires and miscellanies. V. Sciences and Arts.—1. Treatises
